# The 66<sup>th</sup> Annual Meeting of the International Society of Electrochemistry

Green Electrochemistry for Tomorrow's Society  
4-9 October 2015, Taipei, Taiwan

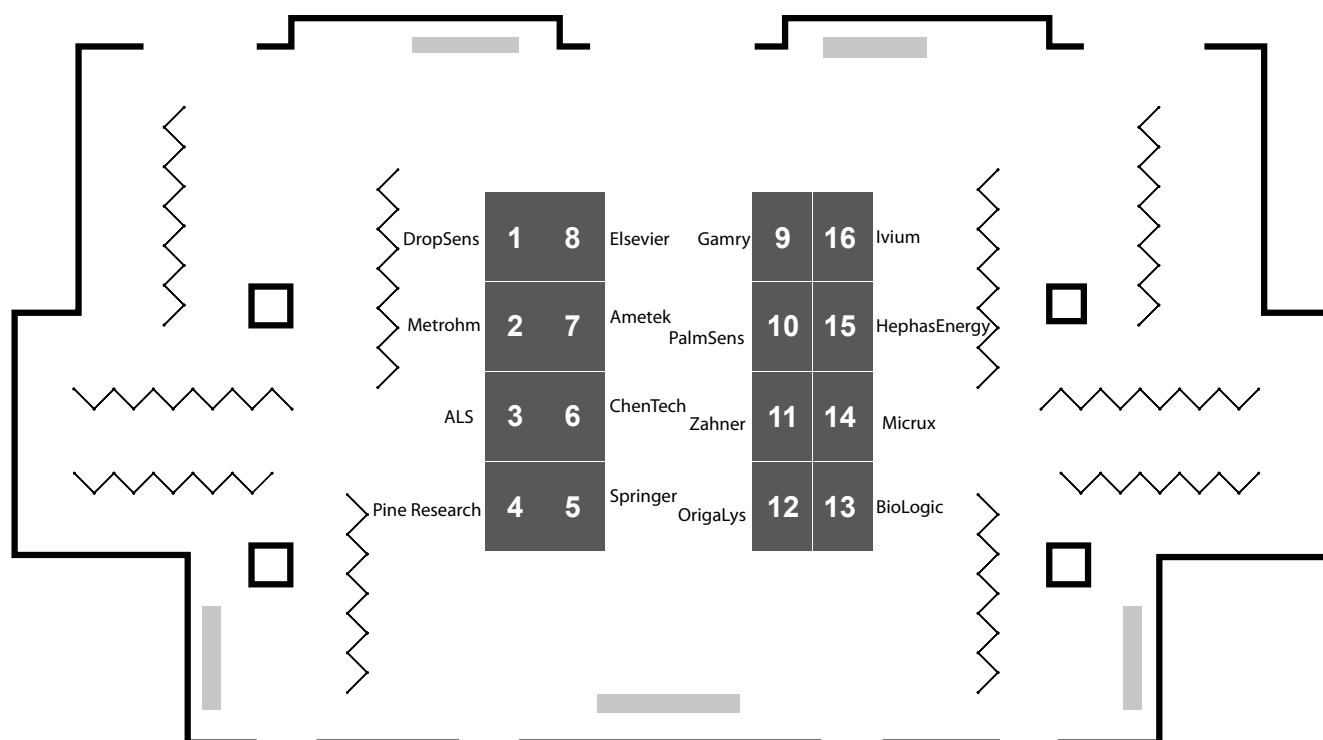

Organized with the contribution of ECSTW   
The Electrochemical Society of Taiwan

## Contents List

Organizing Committee .....	v
Symposium Organizers .....	vi-vii
Tutorial Lectures .....	viii
Author Workshop .....	viii
Plenary Lectures .....	ix
Prize Winners .....	x-xii
ISE Society Meetings .....	xiii
Poster Sessions .....	xiv
General Information .....	inside front cover
Registration Hours during the Meeting .....	inside front cover
On Site Registration Fees .....	inside front cover
Lunches .....	inside front cover
Coffee Breaks .....	inside front cover
Internet Service .....	inside front cover
Accompanying Persons .....	inside front cover
Publications .....	xv
Social Program: Receptions, Excursions and Banquet .....	xv-xvi
Oral Presentation Program	
Monday, 5 October – Friday, 9 October .....	1
Poster Presentation Program - All Symposia .....	81
Author Index .....	140
ISE Society Information .....	159
Poster Plan Session 1 - Monday (Symposia <b>1, 2, 3</b> ) .....	173
Poster Plan Session 2 - Tuesday (Symposia <b>5, 6, 8, 9, 11, 18</b> ) .....	174
Poster Plan Session 3 - Wednesday (Symposia <b>4, 7, 10, 12, 13, 14, 15, 16, 17</b> ) .....	175
Week Schedule .....	176
Symposium Schedule and Floor Plan .....	back cover

## Exhibitor booths

## Exhibition Hours

Monday:	09:30-20:00
Tuesday:	09:30-17:30
Wednesday:	09:30-12:30
Thursday:	09:30-17:30
Friday:	09:30-12:00

## Sponsors

Bureau of Foreign Trade

Ministry of Foreign Affairs  
Republic of China (Taiwan)

Department of Information  
and Tourism

Ministry of Science and Technology

National Taiwan University  
of Science and Technology

Star Alliance

World Scientific Publishing

## Exhibitors

Elsevier

Gamry Instruments

DropSens

IVIUM Technologies

ALS Co. Ltd

Metrohm Autolab

Pine Research Instrumentation

Bio-Logic

Springer

HephasEnergy Co. Ltd.

Origalys

Micrux Fluidic S.L.

PalmSens

Ametek/Princeton/Solartron

Zahner elektrik GmbH&Co

Chen Tech Electric

## Welcome Address

On behalf of the Executive Committee of ISE, the Organizing Committee and Symposium Organizers, we warmly welcome you to Taipei and look forward to your participation in the 66th Annual Meeting of the ISE, “**Green Electrochemistry for Tomorrow’s Society**”, from October 4th to October 9th, 2015. Taipei is the capital city of Taiwan. It was first inhabited by the Ketagalan Tribe hundreds of years ago and now has evolved into an international and high-tech city. Located not far from beautiful coast, Taipei is full of great natural beauty including Maokong, Yangmingshan and hot springs. Taipei is also home to various world-famous architectural or cultural landmarks such as National Palace Museum, Taipei 101, Hsing Tian Kong, Longshan Temple, etc. We hope that you will discover the versatile cultures and experience the Taiwanese hospitality, friendship and vibrant life here. You should definitely reserve some time to walk along the lovely city, explore museums, enjoy the hot springs, stroll down in night markets, have a gentle foot massage, taste a variety of local or fusion cuisine, or simply sip a cup of tea for spiritual tranquility.

Taiwan has a strong tradition in electrochemistry, and scientists in this field have shown significant contribution to academic researches and industrial applications. Nevertheless, the Electrochemical Society of Taiwan (ECSTw) was just founded in 2013 and became one of regional ISE representatives in 2014. The 66th ISE annual meeting is the first ISE conference held ever in Taiwan, but you will expect more ISE conferences hosted by Taiwan in future.

The theme of the 66th ISE annual meeting is planned to address the growing needs for sustainable materials, technologies, processes and applications ranging from energy, environments to food and healthcare in our society. The meeting consists of 18 Symposia sponsored by all Divisions of the ISE. The Symposia organizers have paid a particular attention to preparation of the scientific program to emphasize the most pressing and emerging issues of the field as well as to outline the likely future directions of its development.

“66” means “great success, running smoothly” in local culture. Regardless of all the efforts extended by the Organizing committee, Symposia organizers and Executive Committee so far, the Meeting cannot truly succeed without your participation. We, therefore, sincerely hope that your particular contribution to the scientific program and fruitful discussion will make the 66th Annual ISE Meeting successful and memorable. Finally, we also hope the provided platform and distributed information during the meeting would generate new breakthroughs and in turn furnish a springboard for innovative ideas, future cooperation and new friendship.

*Chair and Secretary General, Organizing Committee, ISE Annual Meeting 2015*

## Organizing Committee

**Christian Amatore, *France***

**Susana Cordoba de Torresi, *Brazil***

**Bing Joe Hwang, *Taiwan (Chair)***

**Manuela Rueda, *Spain***

**Wei-nien Su, *Taiwan (Secretary General)***

**Zhongqun Tian, *China***

**Bernard Tribollet, *France***

**Wei-Ta Tsai, *Taiwan***

**Chi-Chao Wan, *Taiwan***

**Nae-Lih Wu, *Taiwan***

## Symposium Organizers

- Symposium 1: New Directions in Analytical Electrochemistry**  
Lin-Chi Chen (Coordinator), National Taiwan University, Taiwan  
Meng-Jiy Wang, National Taiwan University of Science and Technology, Taiwan  
Alison Downard, University of Canterbury, New Zealand  
Daniel Mandler, The Hebrew University of Jerusalem, Israel
- Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications**  
Damien Arrigan (Coordinator), Curtin University, Australia  
Shen-Ming Chen, National Taipei University of Technology, Taiwan  
Elena Ferapontova, Aarhus University, Denmark  
Mei-Jywan Syu, National Cheng Kung University, Taiwan
- Symposium 3: Batteries for Tomorrow's World**  
Robert Kostecki (Coordinator), Lawrence Berkeley National Laboratory, USA  
She-Huang Wu (Co-coordinator), Tatung University, Taiwan  
Kuniaki Tatsumi, National Inst. of Advanced Industrial Science & Technology, Japan  
Fu-Ming Wang, National Taiwan University of Science and Technology, Taiwan
- Symposium 4: Advances in Fuel Cells from Materials to Systems**  
Hiroyuki Uchida (Coordinator), University of Yamanashi, Japan  
Lorenz Gubler (Co-coordinator), Paul Scherrer Institute, Switzerland  
Kuan-Zong Fung, National Cheng Kung University, Taiwan  
Kuei-Hsien Chen, Institute of Atomic and Molecular Sciences, Taiwan  
Yu-Lin Kuo, National Taiwan University of Science and Technology, Taiwan
- Symposium 5: Novel Insights to Electrochemical Capacitors**  
Hsi-Sheng Teng (Coordinator), National Cheng Kung University, Taiwan  
Chi-Chang Hu (Co-coordinator), National Tsing Hua University, Taiwan  
Elzbieta Frackowiak (Coordinator), Poznan University of Technology, Poland  
Masashi Ishikawa, Kansai University, Japan  
Frédéric Favier, CNRS University of Montpellier 2, France
- Symposium 6: New Progress in Electrochemical Solar Cells**  
Ladislav Kavan (Coordinator), J. Heyrovsky Inst. Physical Chemistry, Czech Republic  
Anders Hagfeldt, Uppsala University, Sweden  
Kuo-Chuan Ho, National Taiwan University, Taiwan  
Jih-Jen Wu, National Cheng Kung University, Taiwan
- Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication**  
Stanko Brankovic (Coordinator), University of Houston, USA  
Massimo Innocenti, University of Florence, Italy  
Nosang Myung, University of California, USA  
Wei-Ping Dow, National Chung Hsing University, Taiwan  
Ming-Der Ger, National Defense University, Taiwan
- Symposium 8: Corrosion and Passivity**  
Nick Birbilis (Coordinator), Monash University, Australia  
Dirk Engelberg, University of Manchester, UK  
Shinji Fujimoto, Osaka University, Japan  
Jing-Chie Lin, National Central University, Taiwan  
Chao-Sung Lin, National Taiwan University, Taiwan
- Symposium 9: Electrocatalytic Materials**  
Kotaro Sasaki (Coordinator), Brookhaven National Laboratory, USA  
Andrew Lin, Chang Gung University, Taiwan  
Chen-Hao Wang, National Taiwan University of Science & Technology, Taiwan  
Anthony Kucernak, Imperial College London, UK

**Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy**

Juan Manuel Peralta-Hernandez (Coordinator), CIATEC, Mexico  
Shi-Chern Yen (Co-coordinator), National Taiwan University, Taiwan  
Manuel Andres Rodrigo, Universidad de Castilla-la-Mancha, Spain  
Alex Peng, Industrial Technology Research Institute, Taiwan

**Symposium 11: New Important Frontiers in Molecular Electrochemistry**

Jirí Ludvík (Coordinator), J. Heyrovský Inst of Physical Chemistry, Czech Republic  
Chun-Hsien Chen (Co-coordinator), National Taiwan University, Taiwan  
Olivier Buriez, CNRS UMR ENS, France  
Flavio Maran, University of Padova, Italy  
Armando Pombeiro, Instituto Superior Tecnico, Portugal

**Symposium 12: Physical Electrochemistry: Spectroscopic, Structural, and Theoretical Investigations of the Electrified Interface**

Andrea Russell (Coordinator), University of Southampton, UK  
Axel Gross, Ulm University, Germany  
Ifan Stephens, Technical University of Denmark, Denmark  
Jyh-Chiang Jiang, National Taiwan University of Science and Technology, Taiwan  
Yuh-Lang Lee, National Cheng Kung University, Taiwan

**Symposium 13: Molecular Systems for Energy Conversion**

Jay Wadhawan (Coordinator), The University of Hull, UK  
Carlos Eduardo Frontana Vazquez, CIDETEQ, Mexico  
Nathan Lawrence, Schlumberger Cambridge Research, UK  
Bluse Ching-Hsing Chen, National Taiwan Univ. Science and Technology, Taiwan

**Symposium 14: Modeling, Design and Characterization of Nanostructured, Electroactive and Multifunctional Materials**

Francesco Paolucci (Coordinator), University of Bologna, Italy  
Pawel J. Kulesza, University of Warsaw, Poland  
Renato Seeber, University of Modena and Reggio Emilia, Italy  
Chin-Lung Kuo, National Taiwan University, Taiwan  
Shirley Meng, University of California San Diego, USA

**Symposium 15: Electrochemical Engineering from a Quantum Description to the Plant Modeling: Experiments and Design across Length Scales**

Alejandro A. Franco (Coordinator), CNRS-University of Picardie, France  
Hung-Lung Chou (Co-coordinator), National Taiwan Univ. Science & Techn, Taiwan  
François Lapique, CNRS and University of Lorraine, France  
Jaeyoung Lee, Gwangju Institute of Science and Technology, Korea

**Symposium 16: Supramolecular Electrochemistry for Analysis, Medicine and Biological Sciences**

Marilia Goulart (Coordinator), Federal University of Alagoas, Brazil  
Stéphane Arbault, University of Bordeaux 1, Pessac, France  
Renata Bilewicz, University of Warsaw, Warsaw, Poland  
Hsien-Chang Chang, National Cheng Kung University, Tainan City, Taiwan  
Chii-Wann Lin, National Taiwan University, Taipei, Taiwan

**Symposium 17: Novel in Situ in Operando Methods**

Hector Abruna (Coordinator), Cornell University, Ithaca, USA  
Patrick Unwin, University of Warwick, Coventry, UK  
Anthony Kucernak, Imperial College London, London, UK  
Michael Eikerling, Simon Fraser University, Burnaby, Canada  
Shawn D. Li, National Taiwan University of Science and Technology, Taipei, Taiwan  
Ming Chang Yang, National Cheng Kung University, Tainan City, Taiwan

**Symposium 18: General Session**

Justin Gooding (Coordinator), The University of New South Wales, Sydney, Australia  
Juan M. Feliu, University of Alicante, Alicante, Spain  
Nae-Lih Wu, National Taiwan University, Taipei, Taiwan  
Liang-Yih Chen, National Taiwan University of Science and Technology, Taipei, Taiwan

---

## Tutorial Lectures and Workshop

---

**Sunday, 4 October 2015**

**Location: TICC**

Taipei International Convention Center

13:30 to 17:00

---

### Tutorial 1

---

**Room 201 AB**

#### Fundamental Aspects and Applications of Cu Electrodeposition

**Rohan Akolkar**, *Case Western Reserve University, USA*

**Peter Broekmann**, *University of Bern, Switzerland*

13:30 to 17:00

---

### Tutorial 2

---

**Room 201 EF**

#### Principles and Applications of in situ in Operando Methods in Electrochemistry

**Neeraj Sharma**, *The University of New South Wales, Australia*

**Bluse Ching-Hsing Chen**, *National Taiwan University of Science and Technology, Taiwan*

13:30 to 17:00

---

### EA Workshop

---

**Room 101 C**

#### Electrochimica Acta / ISE author workshop

**Robert Hillman**, *Editor-in-Chief Electrochimica Acta, University of Leicester, United Kingdom*

15:00 to 15:15

Coffee break

---

## Plenary Lectures

---

**Location: Plenary Hall**

---

### Monday, 5 October 2015

08:15 to 09:15

**Tomokazu Matsue**

*(Tohoku University, Japan)*

Electrochemical Imaging with Micro/Nanoelectrode Systems

### Tuesday, 6 October 2015

08:15 to 09:15

**Hongjie Dai**

*(Stanford University, USA)*

Novel Materials for Renewable Energy

### Wednesday, 7 October 2015

08:15 to 09:15

**Li-Jun Wan**

*(Chinese Academy of Sciences, China)*

Nanomaterials for Energy Conversion and Storage: Structure Design and In-Situ Monitoring

### Thursday, 8 October 2015

08:15 to 09:15

**Martin Winter**

*(Münster University, Germany)*

Neglected, Forgotten or Unimportant? Inactive Materials in Lithium Ion Batteries

### Friday, 9 October 2015

08:15 to 09:15

**Alan Bond**

*(Monash University, Australia)*

A Voltammetric Odyssey: From Homogeneous Dropping Mercury to Heterogeneous Macro and Nano Electrodes; From the Manual Era to Advanced Automated High Speed Computation

---

## ISE Prize Winners 2014

---

### Electrochimica Acta Gold Medal

**Alan Bond**, *Monash University, Australia*

08:15 to 09:15, Friday, 9 October 2015, Plenary Lecture, Plenary Hall

**A Voltammetric Odyssey: From Homogeneous Dropping Mercury to Heterogeneous Macro and Nano Electrodes; From the Manual Era to Advanced Automated High Speed Computation**

The Electrochimica Acta Gold Medal was awarded to Alan Bond for his outstanding and diverse contributions to electrochemical science, spanning innovation in electrochemical techniques, fundamental mechanistic insights and novel materials and media.

### Brian Conway Prize for Physical Electrochemistry

**Masatoshi Osawa**, *Hokkaido University, Japan*

09:30 to 10:10, Monday, 5 October 2015, Symposium 12, Room 101C

**Surface-Enhanced Infrared Absorption Spectroscopy (SEIRAS): Shedding Light on The Electrochemical Interface**

The Brian Conway Prize for Physical Electrochemistry was awarded to Prof. Masatoshi Osawa in recognition of his pioneering work on the development of in situ, time-resolved Surface-Enhanced Infrared Absorption Spectroscopy (SEIRAS).

### Jaroslav Heyrovsky Prize for Molecular Electrochemistry

**Flavio Maran**, *Padova University, Italy*

14:00 to 14:40, Thursday, 8 October 2015, Symposium 11, Room 201D

**Molecular Electrochemistry: from Protons to Electrons, from Molecules to Molecular Nanoclusters**

The Jaroslav Heyrovsky Prize for Molecular Electrochemistry was awarded to Flavio Maran, Padova University, Italy, in recognition of his outstanding contributions to molecular electrochemistry, particularly mechanistic aspects on organic systems and hybrid systems constituted by molecule-like monolayer-protected gold nanoclusters.

### Tajima Prize

**Yu-Guo Guo**, *Chinese Academy of Sciences, China*

09:30 to 10:10, Thursday, 8 October 2015, Symposium 3, Room 201AB

**Advanced Cathodes and Metallic Anodes for Next-Generation Rechargeable Batteries**

The Tajima Prize was awarded to Yu-Guo Guo in recognition of his research activity in electrochemical energy storage with batteries, ion/electron storage and transport in nanoscaled systems kinetics and thermodynamics of nanostructured energy materials.

---

## ISE Prize Winners 2014

---

### Bioelectrochemistry Prize of ISE Division 2

**James Rusling**, *University of Connecticut, USA*

09:30 to 10:10, Monday, 5 October 2015, Symposium 2, Room 101D

**From Protein Film Bioelectrochemistry to Biomedical Devices and Diagnostics**

The Bioelectrochemistry Prize of ISE Division 2 was awarded to James Rusling in recognition of his research activity on thin biosystems for bioelectrochemical applications, direct electron transfer with proteins, bioelectrochemical catalysis, and detection of cancer biomarkers.

### Hans-Jürgen Engell Prize

**Fabio La Mantia**, *Ruhr-Universität Bochum, Germany*

10:10 to 10:30, Tuesday, 6 October 2015, Symposium 3, Room 201AB

**Aqueous Zinc-Ion Batteries based on Prussian Blue Derivatives**

The Hans-Jürgen Engell Prize was awarded to Fabio La Mantia for his excellent contribution to electrochemical materials science in the field of Li-ion batteries.

### Early Career Analytical Electrochemistry Prize of ISE Division 1

**Jan Vacek**, *Palacky University, Olomouc, Czech Republic*

09:30 to 10:10, Thursday 8 October 2015, Symposium 1, Room 103

**Electrochemistry of Membrane Proteins**

The Early Career Analytical Electrochemistry Prize of ISE Division 1 was awarded to Dr. Jan Vacek for his work on new electrochemical methodologies for the analysis of biopolymer interactions and structural modifications, and on electroanalysis of biomolecules.

### ISE Prize for Environmental Electrochemistry

**Sergi Garcia-Segura**, *Barcelona University, Spain*

14:00 to 14:20, Monday 5 October 2015, Symposium 10, Room 101B

**Electrochemical Processes Based on Fenton's Reaction for Wastewater Treatment. An Eco-Friendly, Efficient and Affordable Technology: Then, Now and Tomorrow**

The ISE Prize on Environmental Electrochemistry was awarded to Sergi Garcia Segura in recognition of his contributions on the use of electrochemical advanced oxidation processes for wastewater treatment.

---

## ISE Prize Winners 2014

---

### ISE Prize for Applied Electrochemistry

**Yonggang Wang**, *Key Laboratory of Molecular Catalysis, China*

10:30 to 10:50, Monday, 5 October 2015, Symposium 3, Room 201AB

#### **Aqueous Li (or Na)-ion Batteries for Grid-scale Energy Storage**

The ISE Prize for Applied Electrochemistry was awarded to Yonggang Wang for discovery and characterization of new materials, and invention of energy storage devices.

### Oronzio and Niccolò De Nora Foundation Young Author Prize

**Peng Bai**, *Massachusetts Institute of Technology, USA*

16:40 to 17:00, Thursday, 8 October 2015, Symposium 3, Room 201C

#### **A Solid-Electrolyte-Enabled Lithium-Bromine Flow Battery**

The Oronzio and Niccolò De Nora Young Author Prize was awarded to Bai Peng, author of the article “Statistical kinetics of phase-transforming nanoparticles in LiFePO<sub>4</sub> porous electrodes”, *Electrochimica Acta* 89 (2013) 644– 651 (co-author Guangyu Tian).

### Electrochimica Acta Travel Award Winners 2015

**Wenjing Hong**, *Switzerland*

**Klaus Mathwig**, *the Netherlands*

### ISE Travel Award Winners 2015

**Tso-Fu Mark Chang**, *Japan*

**Marta Costa Figueiredo**, *the Netherlands*

**Javier Llanos**, *Spain*

**Jian-Feng Li**, *China*

**Xiaopeng Li**, *Germany*

**Justus Masa**, *Germany*

**Joaquin Rodriguez-Lopez**, *USA*

**Min-Hsin Yeh**, *USA*

---

## ISE Society Meetings

---

### **Sunday, 4 October 2015**

#### **Opening Ceremony**

17:00 to 18:00 › Plenary Hall

### **Monday, 5 October 2015**

#### **Division Officers Luncheon Meeting**

12:50 to 13:50 › Room 201C

#### **Regional Representatives Luncheon Meeting**

12:50 to 13:50 › Room 201D

### **Tuesday, 6 October 2015**

#### **Council Meeting**

12:50 to 13:50 › Room 201AB

### **Thursday, 8 October 2015**

#### **General Assembly**

11:10 to 12:10 › Plenary Hall

#### **Division Meetings**

12:50 to 13:50

**Division 1 Analytical Electrochemistry › Room 101D**

**Division 2 Bioelectrochemistry › Room 101B**

**Division 3 Electrochemical Energy Conversion and Storage › Room 101C**

**Division 4 Electrochemical Materials Science › Room 102**

**Division 5 Electrochemical Process Engineering and Technology › Room 101A**

**Division 6 Molecular Electrochemistry › Room 201D**

**Division 7 Physical Electrochemistry › Room 201C**

### **Friday, 9 October 2015**

#### **Closing Ceremony**

12:30 to 12:50 › Plenary Hall

*See room locations on back cover*

---

## Poster presentation session 1 - Monday

---

Symposia: 1, 2, 3

Poster set-up Monday: 08:30-10:30 *See poster locations map on page 173*

Poster take-down Monday: 18:00-19:00

**Poster Presentation: Monday, 5 October: 10:50-12:30** (Banquet Hall - 3F)

---

## Poster presentation session 2 - Tuesday

---

Symposia: 5, 6, 8, 9, 11, 18

Poster set-up Tuesday: 08:30-10:30 *See poster locations map on page 174*

Poster take-down Tuesday: 18:00-19:00

**Poster Presentation: Tuesday, 6 October: 10:50-12:30** (Banquet Hall - 3F)

---

## Poster presentation session 3 - Wednesday

---

Symposia: 4, 7, 10, 12, 13, 14, 15, 16, 17

Poster set-up Wednesday: 08:30-10:30 *See poster locations map on page 175*

Poster take-down Thursday: 14:00-16:00

**Poster Presentation: Wednesday, 7 October: 10:50-12:30** (Banquet Hall - 3F)

..

---

## General Information

---

### Publications

A special issue of the Society's journal, *Electrochimica Acta*, is planned based on selected original contributions made at the conference. Selection will be made by an international editorial Committee comprising the following Editors and Guest Editors, one for each of the Symposia in which the meeting is articulated:

Symposium 1 Alison Downard, Symposium 2 Elena Ferapontova, Symposium 3 Robert Kostecki, Symposium 4 Lorenz Gubler, Symposium 5 Chi-Chang Hu, Symposium 6 Ladislav Kavan, Symposium 7 Wei Ping Dow, Symposium 8 Nick Birbilis, Symposium 9 Kotaro Sasaki, Symposium 10 Manuel Andres Rodrigo, Symposium 11 Flavio Maran, Symposium 12 Andrea Russell, Symposium 13 Carlos Eduardo Frontana, Symposium 14 Pawel J. Kulesza, Symposium 15 François Lapicque, Symposium 16 Renata Bilewicz, Symposium 17 Michael Eikerling. The Special Issues Editor, Sergio Trasatti, will co-ordinate the action of the editorial Committee and will be directly responsible for the review procedure. The Special Issue is planned to accommodate ca. 170 papers.

**Submission only on invitation of one of the Guest Editors.**

**Submission timespan: 10 October 2015 - 10 January 2016**

---

## Social Program

---

### RECEPTIONS

#### Welcome Reception

**Sunday, 4 October 2015, 18:00-20:00**

After the Opening Ceremony on floor 1F of the Taipei International Convention Center (TICC)

#### Monday Reception

**Monday, 5 October 2015, 18:40-20:00** on floor 3F in the Taipei International Convention Center (TICC)

#### Tuesday Social Event – Ge Zai Xi (Taiwanese Opera)

(Sponsored by Bureau of Foreign Trade, Ministry of Economic Affairs)

**Tuesday, 6 October 2015, 20:00-21:00**

At the National Taiwan Arts Education Center / No. 47, Nanhai Road, Taipei City

Ticket: US\$ 10.00 had to be booked online during registration

Transportation: MRT Danshui Line (Line 2) to Chiang Kai-Shek Memorial Hall (Exit at No. 1 or 2)

Songshan-Xindian Line (Line 3) to Xiaonamen (Exit at No. 3) [http://www.arte.gov.tw/eng/vist\\_train.asp](http://www.arte.gov.tw/eng/vist_train.asp)

Please check map on inside backcover.

#### Ming Hwa Yuan Arts & Cultural Group

##### About Ge Zai Xi (Taiwanese Opera)

Ge Zai Xi (Taiwanese Opera) is the only performing art form that originated within Taiwan. Because of its origin as folk entertainment, the development and expression of Ge Zai Xi are free from restraints and strict rules of other more formal and traditional performing arts. This all embracing characteristic allowed Ge Zai Xi to develop over the past hundred year into a unique and constantly evolving performing art form which includes fusion of Beijing opera, Gaojia opera, Nanguan and Beiguan as well as modern drama to name a few.

#### Thursday Banquet

**Thursday, 8 October 2015, 19:00**

At the Taipei World Trade Center Club on the 33rd floor. Only 3 walking minutes from the conference center.

<http://www.twtclub.com.tw/en/aboutus.html>

Price: US\$70.00

*Places are limited.*

*All tickets for the Banquet are nonrefundable.*

## EXCURSIONS

### Wednesday, 7 October

You can choose among 6 different excursions that will be organized by Lion Travel on Wednesday afternoon, 7 October 2015. The excursions will depart from the Taipei International Convention Center. Excursions should be pre-booked. Details can be found on the website <http://annual66.isc-online.org/excursions.html>

#### All excursions

Include: Bus rental fee (including Tip for driver), English speaking tour guide.

Travel insurance: NT\$5,000,000 travel industry liability insurance & NT\$200,000 accident medical insurance.

Exclude: Personal expense and meals (Lunch and Dinner)

Special Offer: One bottle of Water and Souvenir

Minimum booking for each tour: 16 persons

#### 1) Tour 1 : Creative Park and Village

Departure from TICC at 13:00

Return at approx 17h10

Price: NTD 1,390 = EUR 40 /per person

#### 2) Tour 2 : Culture of Temples

Departure from TICC at 13:00

Return at approx 17h00

NTD 1,390 = EUR 40 /per person

#### 3) Tour 3 : Culture of Hot Spring

Departure from TICC at 13:00

Return at approx 17h10

NTD 1,390 = EUR 40 /per person

#### 4) Tour 4 : Yingge, Sanxia Ceramics and Temple Tour

Departure from TICC at 13:00

Return at approx 17h00

NTD 1,390 = EUR 40 /per person

#### 5) Tour 5 : Exploring Northern Taiwan !

##### Jiufen Old Street, Gold Waterfall

Departure from TICC at 13:00

Return at approx 17h00

NTD 1,390 = EUR 40 /per person

#### 6) Tour 6 : Culture of Lanyang, Yilan

Departure from TICC at 13:00

Return at approx 18h00

Price: NTD 1,590 = €43/ per person

14:20 - 14:40											
14:40 - 15:00	E. Frackowiak	N. E. Flores Tapia	K. A. Stoerzinger	Seiya Tsujimura	Jin-Song Hu	Bin Ren	Xuejie Huang	H. Koshikawa	Qingh. Zhang	Ping Yu	
15:00 - 15:20	Olivier Crosnier	Ign. González	R. Jinnouchi	Matteo Duca	Tim. Peckham	San. Rondinini	Franz. Mueller	Kotaro Sasaki	Mark. Zukalova	Serge Cosnier	
15:20 - 15:40	Christ. Lethien	B. K. Körbahti	Andy Wain	Ad. De Andrade	Dario Dekel	Eric Sorte	Alvin Wu	Ming Zhou	Jinbao Zhang	Pawel Krynsinski	
15:40 - 16:00	Hiroshi Inoue	Minghua Zhou	M. Figueiredo	Paul Bernhardt	Jingshuai Yang	Sarah Day	Eunseog Cho	YuYe Tong	Kuan-JiuH Lin	D. Matyszcwska	
16:00 - 16:20	Abdulc. Yavuz	Ali Farhat	Sunny Hy		Yu Yang	Simon Thiele	Andrew Gewirth	Justus Masa	Ladislav Kavan	Lars Jeuken	
16:20 - 16:40	Coffee Break										
16:40 - 17:00	Daniel Bélanger	Yunny Meas	Zhong-Qun Tian	Alain Walcarlus	P. Lettenmeier	Mario El Kazzi	Mark Orazem	Atsun. Ikezawa	Peter Deák	Rich. Compton	
17:00 - 17:20	Keryn Lian		Masato Tominaga	Elisabeth Lojou	Yeh-Hung Lai	Misun Hong	Wei Kong Pang	Samuel Perry	Flor. Le Formal		
17:20 - 17:40	Yuan Chen	K. Petrov	Shino Sato	Enrico Marsili	Lin Gan	Yosh. Uchimoto	J. M. Paz-Garcia	Lior Elbaz	Pauline Bornoz	Enno Käthehöhn	
17:40 - 18:00	Peihua Huang	Hui-Wen Lin	Juan M. Feliu	M. Karaskiewicz	Ken. Ozoemena	Neeraj Sharma	Klaus Wedlich	Ci. Zafferoni	Yan-Gu Lin	Marcin Opallo	
18:00 - 18:20	Wat. Sugimoto	Olivier Lefebvre	Robert Hillman	Lo Gorton	K. Boni. Kokoh	Hector Abruna	S. Pradanawati	Daniel Scherson	Maur. Schieda	Hua Cui	
18:20 - 18:40	Dah-Shy. Tsai	K. Kawaguchi	K. Motobayashi	W. Schuhmann	Wenjing Zhang		Jianbo Zhang	Minhua Shao	Kenji Sakamaki	Fred Lisdat	
18:40 - 20:00	Reception										

# Monday, 5 October 2015 - Morning

## Plenary Lecture

**Room : Plenary Hall**

*Chaired by:* Ken-ichiro Ota

08:15 to 09:15

**Tomokazu Matsue** (WPI-Advanced Institute for Materials Research, Tohoku University, Sendai, Japan)

[Electrochemical Imaging with Micro/Nanoelectrode Systems](#)

## Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications

**Room : 101D**

*Chaired by:* Renata Bilewicz and Karen Monsalve

09:30 to 10:10 Keynote **Bioelectrochemistry Prize of ISE Division 2**

**James Rusling** (Chemistry, University of Connecticut, Storrs, USA)

[From Protein Film Bioelectrochemistry to Biomedical Devices and Diagnostics](#)

10:10 to 10:30

**Benoît Piro** (Chemistry, University Paris Diderot, Lab. ITODYS, Ivry-sur-Seine, France), Malika Souada, Steve Reisberg, Guillaume Anquetin, Vincent Noël, Minh-Chau Pham

[Label-free Electrochemical Detection of Prostate-Specific Antigen based on Nucleic Acid Aptamer](#)

10:30 to 10:50

**Xing-Hua Xia** (School of Chemistry and Chemical Engineering, Nanjing University, Nanjing, China)

[Manipulation of biomolecular functions at electrode surfaces via surface modification](#)

10:50 to 11:10

Coffee Break

## Symposium 3: Batteries for Tomorrow's World

**Room : 201AB**

*Chaired by:* Robert Kostecki

09:30 to 10:10 Keynote

**Petr Novak** (Paul Scherrer Institut, Electrochemical Energy Storage Section, Villigen PSI, Switzerland), Peter Bleith, Rosa Robert, Tsuyoshi Sasaki, Claire Villevieille

[How to Understand the Electrochemistry of Battery Materials?](#)

10:10 to 10:30 Invited

**Minoru Inaba** (Department of Molecular Chemistry and Biochemistry, Doshisha University, Kyotanabe, Japan), Rin Masuhara, Yusuke Shimizu, Michihiro Hashinokuchi, Takayuki Doi

[Highly Concentrated Electrolytes for 5-V Cathodes](#)

10:30 to 10:50 Invited **ISE Prize for Applied Electrochemistry**

**Yonggang Wang** (Department of Chemistry, Fudan University, Shanghai, China), Yongyao Xia

[Aqueous Li \(or Na\)-ion Batteries for Grid-scale Energy Storage](#)

10:50 to 11:10

Coffee Break

## Symposium 4: Advances in Fuel Cells from Materials to Systems

Room : 102

Chaired by: Kenichiro Ota

09:30 to 09:50 Invited

**Kenichiro Ota** (Green Hydrogen Research Center, Yokohama National University, Yokohama, Japan), Koichi Matsuzawa, Shigenori Mitsushima, Akimitsu Ishihara

[Challenges of NPGM Oxide Cathode for PEFCs](#)

09:50 to 10:10

**Akimitsu Ishihara** (Institute of Advanced Sciences, Yokohama National University, Yokohama, Japan), Makoto Hamazaki, Tomoaki Hayashi, Yuko Tamura, Yuji Kohno, Koichi Matsuzawa, Shigenori Mitsushima, Hideto Imai, Kenichiro Ota

[Proposal of Oxide-Based Compounds as Non-Platinum Group Metals and Carbon-Free Cathodes for Polymer Electrolyte Fuel Cells](#)

10:10 to 10:30

**Chang Hyuck Choi** (Department of Interface Chemistry and Surface Engineering, Max-Planck-Institut für Eisenforschung, Düsseldorf, Germany), Karl Mayrhofer

[Operando degradation studies of Fe-N-C catalysts in acid electrolyte](#)

10:30 to 10:50

**Xiaodong Yang** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China)

[Liquid Fuel Cells with Polymer Fiber Membrane and Non-precious Metal Catalysts](#)

10:50 to 11:10

Coffee Break

## Symposium 5: Novel Insights to Electrochemical Capacitors

Room : 101A

Chaired by: Chi-Chang Hu

09:30 to 10:10 Keynote

**Katsuhiko Naoi** (Department of Applied Chemistry, Tokyo University of Agriculture & Technology, Tokyo, Japan)

["Nanohybrid Capacitor" -Future Projection for Gen.II Supercapacitors-](#)

10:10 to 10:30 Invited

**George Zheng Chen** (Department of Chemical and Environmental Engineering, University of Nottingham Ningbo China, Ningbo, China)

[On Combined Capacitive and Nernstian Mechanisms for Improved Electrochemical Energy Storage](#)

10:30 to 10:50

**Chinwe Ikpo** (Chemistry, University of the Western Cape, Cape Town, South Africa), Ntuthuko Hlongwa, Kenneth Ozoemena, Emmanuel Iwuoha, Natasha Ross, Miranda Ndipingwi, Myra Nzaba, Milua Masikini, Nolubabalo Matinise, Nomxolisi Dywili, Priscilla Baker

[Lithium Manganese Phosphate-gold Nanoparticles Composite as an Efficient Lithium Ion Electrochemical Capacitor](#)

10:50 to 11:10

Coffee Break

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 201EF**

*Chaired by:* Kotaro Sasaki

09:30 to 10:10 Keynote

**Piotr Zelenay** (Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos, USA)

[Non-Precious Metal Catalysts for Oxygen Reduction: Accomplishments and Challenges](#)

10:10 to 10:30

**Yuto Miyahara** (Graduate School of Engineering, Kyoto University, Kyoto, Japan), Kohei Miyazaki, Tomokazu Fukutsuka, Takeshi Abe

[Catalytic Activities of Perovskite-type Oxide Thin Films and Single Crystals as Oxygen Electrodes in Alkaline Media](#)

10:30 to 10:50

**Federico Tasca** (Department of Chemistry of Materials, University of Santiago of Chile, Santiago, Chile), Javier Recio, Jose Zagal, Nataly Silva, Carmen Castro, Cesar Zuñiga, Maria Oyarzun

[O<sub>2</sub> Reduction at Graphite Electrodes Modified with MN<sub>4</sub> Macrocyclic Complexes and Pyridine Grafted Carbon Nanotubes](#)

10:50 to 11:10

Coffee Break

---

## Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy

---

**Room : 101B**

*Chaired by:* Geoff Kelsall and Philippe Vernoux

09:30 to 10:10 Keynote

**Guohua Chen** (Department of Chemical and Biomolecular Engineering, The Hong Kong University of Science and Technology, Hong Kong, China), Ping Geng

[Magnéli Ti<sub>4</sub>O<sub>7</sub> Modified Ceramic Membrane for Electrically-assisted Filtration with Antifouling Property](#)

10:10 to 10:30

**Miguel Sandoval** (Department of Chemical Engineering, University of Guanajuato, Guanajuato, Mexico), Rosalba Fuentes, José L. Nava, Israel Rodríguez

[Fluoride Removal from Drinking Water by Electrocoagulation in a Continuous Filter Press Reactor coupled to a Flocculator and Clarifier](#)

10:30 to 10:50

**Tsuyoshi Hoshino** (Japan Atomic Energy Agency, Japan Atomic Energy Agency, 2-166 Obuchi, Omotedate, Rokkasho-mura, Japan)

[Development of Lithium Recovery Technique from Seawater by using Innovative Electrodialysis with Lithium Ionic Superconductor](#)

10:50 to 11:10

Coffee Break

## Symposium 12: Physical Electrochemistry: Spectroscopic, Structural, and Theoretical Investigations of the Electrified Interface

**Room : 101C**

*Chaired by:* Masatoshi Osawa and Ifan Stephens

### 09:30 to 10:10 Keynote **Brian Conway Prize for Physical Electrochemistry**

**Masatoshi Osawa** (Catalysis Research Center, Hokkaido University, Sapporo, Japan)

[Surface-Enhanced Infrared Absorption Spectroscopy \(SEIRAS\): Shedding Light on The Electrochemical Interface](#)

10:10 to 10:30

**Ye Wang** (Department of Chemistry, Fudan University, Shanghai, China), Wen-Bin Cai

[Enhanced Electrocatalysis of Ethanol on Dealloyed Pd-Ni-P Film in Alkaline Media: an Infrared Spectroelectrochemical Investigation](#)

10:30 to 10:50

**Kun Jiang** (Department of Chemistry, Fudan University, Shanghai, China), Sylvain Brimaud, Wen-Bin Cai, R. Jürgen Behm

[C1 Molecule Adsorption-Dissociation on Pt and Cu-modified Pt Electrode Surfaces](#)

10:50 to 11:10

Coffee Break

## Symposium 13: Molecular Systems for Energy Conversion

**Room : 201C**

*Chaired by:* Nam-Gyu Park and Xinhua Zhong

09:30 to 09:50 Invited

**Nam-Gyu Park** (School of Chemical Engineering and Dept. of Energy Science, Sungkyunkwan University, Suwon, Korea)

[Methodologies for 20% Efficient Perovskite Solar Cells](#)

09:50 to 10:10

**Xinhua Zhong** (Institute of Applied Chemistry, East China University of Science and Technology, Shanghai, China)

[Ligand Induced Self-Assembly for High Efficiency Quantum Dot Sensitized Cells](#)

10:10 to 10:30

**Yu-Tung Yin** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei City, Taiwan)

[Impedance Spectroscopic Analysis of Organic-Inorganic Hybrid Perovskite Solar Cell under Different Architectures](#)

10:30 to 10:50

**Liang-Che Chen** (Chemical Engineering, National Cheng Kung University, Tainan, Taiwan) Te-Fu Yeh, Chiao-Yi Teng, Hsisheng Teng

[Graphene Oxide Quantum Dots for Photon Energy Conversion](#)

10:50 to 11:10

Coffee Break

---

## Symposium 16: Supramolecular Electrochemistry for Analysis, Medicine and Biological Sciences

---

**Room : 201D**

*Chaired by:* Marilia Goulart and Hsien-Chang Chang

09:30 to 09:50 Invited

**Olivier Buriez** (Ecole Normale Supérieure, CNRS, Paris, France)

[Contribution of Electrochemistry to Investigate the Solubilization and Transport Through Suspended Membranes of Redox Active Molecules](#)

09:50 to 10:10

**Joanna Juhaniewicz** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Dorota Konarzewska, Michal Jamroz, Slawomir Sek

[Application of Natural Cationic Peptides as Potential Antibacterial Agents](#)

10:10 to 10:50 Keynote

**R. Daniel Little** (Chemistry and Biochemistry, University of California Santa Barbara, Santa Barbara, USA), Seung Joon Yoo, Sebastian Herold, Long-Ji Li, Cheng-Chu Zeng

[A Recyclable Reaction Medium: Applications to Oxidative and Reductive Organic Electrochemical Transformations](#)

10:50 to 11:10

Coffee Break

---

## Symposium 17: Novel in Situ in Operando Methods

---

**Room : 103**

*Chaired by:* Michael Eikerling and Ming-Chang Yang

09:30 to 09:50

**Zhi-You Zhou** (Department of Chemistry, Xiamen University, Xiamen, China), Yu-Hao Hong, Tian Sheng, Jian-Long Lin, Jie Ren, Sheng-Pei Chen, Shi-Gang Sun

[Electrooxidation mechanism of NH<sub>3</sub> on Pt by in situ FTIR reflection spectroscopy](#)

09:50 to 10:10

**Yi-Fan Huang** (Chemistry, Leiden University, Leiden, Netherlands), Marc T.M. Koper

[In-situ identification of electrochemical oxidation of Pt\(111\) and Pt\(100\) by Raman spectroscopy assisted by DFT calculation](#)

10:10 to 10:30

**Long Huang** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China), Eric Sorte, Yuye Tong, Shi-Gang Sun

[In-situ <sup>13</sup>C NMR spectroscopy study of ethanol electro-oxidation on Pt and PtRu](#)

10:30 to 10:50

**Fabian Kubannek** (Institute of Energy and Process Systems Engineering, TU Braunschweig, Braunschweig, Germany), Ulrike Krewer

[From Quantitative Differential Electrochemical Mass Spectrometry Experiments to Electrochemical Surface Reaction Models](#)

10:50 to 11:10

Coffee Break

# Monday, 5 October 2015 - Afternoon

MONDAY PM

## Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications

Room : 101D

Chaired by: Liza Rassaei, Mei-Jywan Syu and Jan Vacek

14:00 to 14:20 Invited

**Sean Elliott** (Department of Chemistry, Boston University, Boston, USA), Kathryn Bewley, Evan Judd, Kelly Walsh, Lindsey Walker

[Diversity and Electrocatalysis by Multi-heme Cytochromes c](#)

14:20 to 14:40

**Ross Milton** (Department of Chemistry, University of Utah, Salt Lake City, USA), David Hickey, Sofiene Abdellaoui, Koun Lim, Boxuan Tan

[Naphthoquinone Derivatives as Low-Potential Electron Mediators of FAD-Dependent Glucose Dehydrogenase](#)

14:40 to 15:00

**Seiya Tsujimura** (Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan)

[Biocathode based on a MgO-template Carbon Electrode Modified with ABTS and Bilirubin Oxidase](#)

15:00 to 15:20

**Matteo Duca** (Department of Chemistry, University of Oxford, Oxford, United Kingdom), Justin Weeks, Justin Fedor, Joel Weiner, Kylie Vincent

[Electrocatalytic cascades driven by enzymes and metal nanoparticles on carbon supports: the reduction of nitrate to ammonia at neutral pH](#)

15:20 to 15:40

**Adalgisa De Andrade** (Chemistry, FFCLRP/USP, Universidade de São Paulo, Ribeirao Preto, Brazil), Sidney Aquino-Neto, David Hickey, Ross Milton, Shelley Minter

[High Current Density Bioanodes for Ethanol Oxidation using PQQ-dependent Enzymes](#)

15:40 to 16:20 Keynote

**Paul Bernhardt** (School of Chemistry and Molecular Biosciences, University of Queensland, Brisbane, Australia)

[Molybdenum Enzyme Electrochemistry](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Alain Walcarius** (LCPME - CNRS, CNRS and Lorraine University, Villers-les-Nancy, France)

[Bioelectrocatalysis with sol-gel biocomposite layers deposited onto porous electrodes](#)

17:00 to 17:20

**Elisabeth Lojou** (BIP-CNRS, CNRS-AMU, Marseille, France), Anne de Poulpique, Karen Monsalve, Christian Kjaergaard, Ed Solomon, Nicolas Mano

[Thermostable enzymes for biofuel cells: wiring strategies and inhibitor influence](#)

17:20 to 17:40

**Enrico Marsili** (Singapore Centre on Life Sciences Engineering, Nanyang Technological University, Singapore, Singapore), Abeed Fatima Binti Mohidin Batcha, Kannan Palanisamy, Carlo Santoro, Maria Yung, Thomas Seviour, Jamie Hinks, Federico Lauro

[Detection of semivolatile organic compounds \(VOCs\) in wastewater through current output of electrochemically active bacteria](#)

17:40 to 18:00

**Maciej Karaskiewicz** (College of Inter-Faculty Individual Studies in Mathematics, University of Warsaw, Warsaw, Poland), Jerzy Rogalski, Renata Bilewicz, Jacek Lipkowski

[Probing Laccase Immobilization on Modified Gold Electrodes and Conformational Changes by Surface-Enhanced Infrared Absorption Spectroscopy](#)

18:00 to 18:20

**Lo Gorton** (Dept. of Biochemistry and Structural Biology, Lund University, Lund, Sweden)

[Electrochemical Communication between Photosynthetic Membranes/Cells and Electrodes](#)

18:20 to 18:40

**Wolfgang Schuhmann** (Analytical Chemistry, Center for Electrochemical Sciences, Ruhr-Universität Bochum, Bochum, Germany), Adrian Ruff, Piyanut Pinyou, Sabine Alsaoub, Fangyuan Zhao, Francesco Lopez, Stefan Barwe, Nikola Markovic, Corina Andronescu, Nicolas Plumeré

[Redox polymers @ bioelectrochemistry. From biosensors to biofuel cells and self-powered bioelectrochemical devices](#)

---

## Symposium 3: Batteries for Tomorrow's World

---

**Room : 201AB**

*Chaired by:* Petr Novak

14:00 to 14:40 Keynote

**Zempachi Ogumi** (Office of Society-Academia Collaboration for Innovation, Kyoto University, Gokasho, Uji, Japan), Hajime Arai, Yoshiharu Uchimoto

[Reactions in cathode positive composite electrode by using synchrotron X-ray](#)

14:40 to 15:00 Invited

**Xuejie Huang** (Institute of Physics, Chinese Academy of Sciences, Beijing, China)

[High Voltage Cathode Materials  \$\text{LiNi}\_{0.5}\text{Mn}\_{1.5}\text{O}\_4\$  for Li-ion Batteries](#)

15:00 to 15:20

**Franziska Mueller** (Helmholtz Institute Ulm, Karlsruhe Institute of Technology, Ulm, Germany), Dominic Bresser, Ulderico Ulissi, Stefano Passerini

[Advanced Anode Materials combining Conversion & Alloying Energy Storage Mechanism for Lithium-Ion Batteries](#)

15:20 to 15:40

**Alvin Wu** (R&D, Underwriters Laboratories Taiwan Co., Ltd., Taipei, Taiwan)

[Explore the Failure Mechanism in Lithium-ion Batteries by Forensic Analysis Techniques](#)

15:40 to 16:00

**Eunseog Cho** (Samsung Advanced Institute of Technology, Samsung Electronics, Suwon, Korea), Kihong Kim, Changhoon Jung, Hyo Sug Lee, Kyoungmin Min, Woo Sung Jeon, Gyeong-Su Park, Jaikwang Shin

[The role of the oxygen in the  \$\text{Li}\_2\text{MnO}\_3\$  cathode material for the Li-ion batteries](#)

16:00 to 16:20

**Andrew Gewirth** (Chemistry, University of Illinois, Urbana, USA)

[Electrochemical Stiffness in Lithium Ion Batteries](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Mark E. Orazem** (Department of Chemical Engineering, University of Florida, Gainesville, USA), Salim Erol

[The Influence of Anomalous Diffusion on the Impedance Response of  \$\text{LiCoO}\_2/\text{C}\$  Batteries](#)

17:00 to 17:20

**Wei Kong Pang** (Bragg Institute, Australian Nuclear Science and Technology Organisation, Kirrawee DC, Australia), Vanessa K. Peterson

[Characterisation of Electrode Materials for Li-Ion Batteries Using Operando Neutron Powder Diffraction](#)

17:20 to 17:40

**Juan Manuel Paz-Garcia** (Division of Solid Mechanics, Lund University, Lund, Sweden), Oluwadamilola O. Taiwo, Paul R. Shearing, Donal Finegan, Rajmund Mokso, Erika Tudisco, Matti Ristinmaa, Stephen Hall

[Electrochemical-mechanical Coupled Phenomena in Silicon-based Li-ion Batteries Using X-ray Tomographic Characterization](#)

17:40 to 18:00

**Klaus Wedlich** (Institute of Energy and Climate Research (IEK-3), Forschungszentrum Jülich, Jülich, Germany), Carsten Korte, Detlef Stolten

[Investigation of the growth of a SEI-like surface layer on LiNi<sub>0.5</sub>Mn<sub>1.5</sub>O<sub>4</sub> high voltage cathodes](#)

18:00 to 18:20

**Sylvia Ayu Pradanawati** (Graduate Institute of Applied Science, National Taiwan University of Science and Technology, Taipei, Taiwan), Fu-Ming Wang

[In-Situ Observation of Solid Electrolyte Interphase \(SEI\) Formation in Electrochemical Surface Plasma Resonance \(EC-SPR\)](#)

18:20 to 18:40 Invited

**Jianbo Zhang** (Dept of Automotive Engineering, Tsinghua University, Beijing, China), Jun Huang, Zhe Li

[Characterizing Interfacial and Bulk Phase Processes in LIB Using EIS](#)

---

## Symposium 4: Advances in Fuel Cells from Materials to Systems

---

**Room : 102**

*Chaired by:* Dario Dekel and Timothy J. Peckham

14:00 to 14:20

**Zidong Wei** (School of Chemistry and Chemical Engineering, Chongqing University, Chongqing, China), Wei Ding, Li Li, Siguo Chen, Xueqiang Qi

[Pt-free Catalyst for Oxygen Reduction Reaction in Fuel Cells](#)

14:20 to 14:40

**Hsin-Chih Huang** (Department of Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Sun-Tang Chang, Chen-Hao Wang, Li-Chyong Chen, Kuei-Hsien Chen

[High Activity Pyrolyzed Iron-FA as Potential Pt-Substitute for Oxygen Reduction Reaction](#)

14:40 to 15:00

**Jin-Song Hu** (Institute of Chemistry, Chinese Academy of Sciences, Beijing, China), Zidong Wei, Li-Jun Wan

[Designing Efficient Nanocatalysts for Oxygen Reduction Reaction](#)

15:00 to 15:20 Invited

**Timothy J. Peckham** (Department of Chemistry, Simon Fraser University, Burnaby, Canada), Andrew G. Wright, Owen D. Thomas, Mahesh P. Kulkarni, Kristen J.W.Y. Soo, Steven Holdcroft

[Membranes with Potential AAEMFC Applications: Structure-Property Relationships of Methylated Poly\(benzimidazole\)s](#)

15:20 to 15:40 Invited

**Dario Dekel** (Chemical Engineering, Technion - Israel Institute of Technology, Haifa, Israel)

[Review of the Latest Advances and Current Challenges of Anion Exchange Membrane Fuel Cell Technology](#)

15:40 to 16:00

**Jingshuai Yang** (Department of Chemistry, Northeastern University, Shenyang, China)

[Preparation and Properties of PTFE Reinforced Novel Anion Exchange Membranes Based on Silane Crosslinked Imidazolium Containing Poly\(2,6-dimethyl-1,4-phenylene oxide\)](#)

16:00 to 16:20

**Yu Yang** (Department of Materials Science and Technology, Nagaoka University of Technology, Nagaoka, Japan), Sayoko Shironita, Kunio Nakatsuyama, Kenichi Souma, Minoru Umeda

[Corrosion Characteristics of Ni-free Nitriding Stainless Steel as Bipolar Plate Material for PEFC](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Philipp Lettenmeier** (Institute of Engineering Thermodynamics, German Aerospace Center, Stuttgart, Germany), Rainey Wang, Rami Abouatallah, Aldo Saul Gago, Kaspar Andreas Friedrich

[Durable MEAs for PEM electrolyser systems operating at high current densities](#)

17:00 to 17:20

**Yeh-Hung Lai** (Fuel Cell Research and Development, General Motors Company, Pontiac, USA), Corey P Schaffer

[Shorting in Proton Exchange Membrane Fuel Cells](#)

17:20 to 17:40

**Lin Gan** (Division of Energy and Environment, Graduate School at Shenzhen, Tsinghua University, Shenzhen, China), Chunhua Cui, Fabio Dionigi, Peter Strasser

[Shaped Pt Bimetallic Nanoparticles: Linking the Anisotropic Growth to the Electrocatalytic Properties](#)

17:40 to 18:00

**Kenneth Ozoemena** (Materials Science and Manufacturing, Council for Scientific and Industrial Research (CSIR), Pretoria, South Africa)

[Novel Pd-Fe-Co Core-Core-Shell Anode Nanocatalyst in Alkaline Anion-Exchange Membrane Alcohol Fuel Cells](#)

18:00 to 18:20

**Kouakou Boniface Kokoh** (Chemistry, University of Poitiers / IC2MP, Poitiers, France), Roberta Alvarenga Isidoro, Elisabete Inacio Santiago, Nihat Ege Sahin, Teko W. Napporn

[Effective Pd-based Electrode Nanomaterials for H<sub>2</sub>/O<sub>2</sub> Solid Polymer Electrolyte Fuel Cells](#)

18:20 to 18:40

**Wenjing (Angela) Zhang** (Department of Energy Conversion and Storage, Technical University of Denmark, Ros, Denmark), Debora Marani, Rafael Hubert Silva, Rebecka Maria Larsen Wercheister, Kent Kammer Hansen, Vincenzo Esposito

[Electrospun Nanofiber Catalysts for Green Technology](#)

## Symposium 5: Novel Insights to Electrochemical Capacitors

Room : 101A

*Chaired by:* George Zheng Chen, Yury Gogotsi, Kwang-Bum Kim and Katsuhiko Naoi

14:00 to 14:40 Keynote

**Yury Gogotsi** (Drexel University, Materials Science and Engineering, A.J. Drexel Nanomaterials , Philadelphia, USA)

[Two-Dimensional Materials and Electrode Architectures for Capacitive and Pseudocapacitive Energy Storage](#)

14:40 to 15:00 Invited

**Elzbieta Frackowiak** (Institute of Chemistry and Technical Electrochemistry, Poznan University of Technology, Poznań, Poland), Adam Kolodziej, Krzysztof Fic

[Towards Green Aqueous Capacitors with Chitin as Binder](#)

15:00 to 15:20

**Olivier Crosnier** (CNRS - IMN, University of Nantes, Nantes, France), Nicolas Goubard, Frédéric Favier, Christophe Payen, Philippe Leone, Thierry Brousse

[FeWO<sub>4</sub> as a new high volumetric capacitance material for aqueous electrochemical supercapacitors](#)

15:20 to 15:40

**Christophe Lethien** (IEMN - RS2E, Université Lille, Villeneuve d'ascq, France), Kevin Brousse, Etienne Eustache, Peihua Huang, Camille Douard, Barbara Daffos, Pierre Louis Taberna, Jean Le Bideau, Thierry Brousse, Patrice Simon

[On chip 3D pseudocapacitive and carbon based electrochemical microsupercapacitors at the wafer level](#)

15:40 to 16:00

**Hiroshi Inoue** (Applied Chemistry, Osaka Prefecture University, Sakai, Japan), Kentaro Konishi, Eiji Higuchi, Masanobu Chiku

[Electrochemical Characterization of an Aqueous Hybrid Capacitor with Zinc and Activated Carbon Electrodes](#)

16:00 to 16:20

**Abdulcabbar Yavuz** (Department of Chemistry, University of Leicester, Leicester, United Kingdom), Robert Hillman, Karl S. Ryder

[Ion Exchange Optimization of Polyaniline Films in Deep Eutectic Solvents for Supercapacitor Application](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Daniel Bélanger** (Chimie, Université du Québec à Montréal, Montréal, Canada), Galyna Shul

[New materials for electrochemical capacitors](#)

17:00 to 17:20 Invited

**Keryn Lian** (Department of Materials Science and Engineering, University of Toronto, Toronto, Canada), Matthew Genovese, Yeewei Foong

[Design and Modification of Inorganic/Organic Polyoxometalates-Carbon Pseudocapacitive Electrodes](#)

17:20 to 17:40 Invited

**Yuan Chen** (School of Chemical and Biomedical Engineering, Nanyang Technological University, Singapore, Singapore)

[Micro-supercapacitors based on carbon hybrid fibers](#)

17:40 to 18:00

**Peihua Huang** (CIRIMAT, Université Paul Sabatier, Toulouse, France), Kevin Brousse, Christophe Lethien, Marc Respaud, Yury Gogotsi, Pierre-Louis Taberna, Patrice Simon

[On-chip Carbide Derived Carbon Thin Films for Microsupercapacitors](#)

18:00 to 18:20 Invited

**Wataru Sugimoto** (Center for Energy and Environmental Science, Shinshu University, Ueda, Japan), Sho Makino

[Pseudocapacitance of ruthenium oxide in buffered solutions](#)

18:20 to 18:40

**Dah-Shyang Tsai** (Chemical Engineering Department, National Taiwan University of Science and Technology, Taipei, Taiwan)

[Structure and Capacity of a Tin-Copper-CNT Composite Anode and its Lithium Ion Hybrid Capacitor Performance](#)

---

## Symposium 6: New Progress in Electrochemical Solar Cells

---

**Room : 201C**

*Chaired by:* Kuei-Hsien Chen, Ib Chorkendorff, Florian Le Formal and Chen-Yu Yeh

14:00 to 14:20 Keynote

**Chen-Yu Yeh** (Chemistry, National Chung Hsing University, Taichung, Taiwan)

[Recent Progress of Porphyrin-Sensitized Solar Cells](#)

14:20 to 14:40

**Hyunwoong Seo** (Information Science and Electrical Engineering, Kyushu University, Fukuoka, Japan), Min-Kyu Son, Shinji Hashimoto, Naho Itagaki, Kazunori Koga, Masaharu Shiratani

[Novel polymer counter electrode of dye-sensitized solar cells](#)

14:40 to 15:00

**Qinghong Zhang** (State Key Laboratory for Modification of Chemical Fibers, Donghua University, Shanghai, China)

[Some Chemical Routes to Form Compact Films of Dye-sensitized Solar Cells](#)

15:00 to 15:20

**Marketa Zukalova** (Electrochemical Materials, J. Heyrovsky Institute of Physical Chemistry, AS CR, Prague, Czech Republic), Ladislav Kavan, Milan Bousa, Zdenek Bastl, David Havlicek

[Sol-gel TiO<sub>2</sub> blocking layers for dye-sensitized and perovskite solar cells: Electrochemical properties and electrochemical doping](#)

15:20 to 15:40

**Jinbao Zhang** (Chemistry, Uppsala University, Uppsala, Sweden), Nick Vlachopoulos, Erik Johansson, Mohamed Jouini, Gerrit Boschloo, Anders Hagfeldt

[In-situ Photoelectrochemical Polymerization Approach For Efficient Solid-state Dye Sensitized Solar Cells](#)

15:40 to 16:00

**Kuan-Jiuh Lin** (Department of Chemistry, National Chung-Hsing University, Taichung, USA), Yin-Cheng Yen

[Plasmon-Induced Efficiency Enhancement on Dye-Sensitized Solar Cell by a TNW-AuNP Layer](#)

16:00 to 16:20

**Ladislav Kavan** (Electrochemical Materials, J. Heyrovsky Institute of Physical Chemistry, Prague 8, Czech Republic), Zuzana Vlckova-Zivcova, Hana Krysova, Petr Cigler, Paul Liska, Shaik M. Zakeeruddin, Michael Grätzel

[Novel Cathode and Photocathode Materials for Dye-Sensitized Solar Cells](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Peter Deák** (BCCMS, University of Bremen, Bremen, Germany), Jolla Kullgren, Balint Aradi, Thomas Frauenheim, Ladislav Kavan

[Resolving the Controversy about the Band Alignment between Rutile and Anatase: the Role of OH<sup>-</sup>/H<sup>±</sup> Adsorption](#)

17:00 to 17:20 Invited

**Florian Le Formal** (Institute of Chemical Science and Engineering (LIMNO), Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland), Mathieu Prévot, Xiaoyun Yu, Wiktor S. Bourée, Nestor Guizarro, Kevin Sivula

[Solution-Processed Nanostructured p-type Photocathodes for Solar Hydrogen Production](#)

17:20 to 17:40

**Pauline Borno** (Institute of Chemistry and Chemical Engineering, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland), Mathieu Prévot, Xavier Jeanbourquin, Kevin Sivula

[An Organic Semiconductor as a Photoanode for Solar Water Splitting](#)

17:40 to 18:00

**Yan-Gu Lin** (Scientific Research Division, National Synchrotron Radiation Research Center, Hsinchu, Taiwan), Hong-Jhe Lin, Yu-Chang Lin

[Earth-Abundant Materials for Photocatalytic Water splitting](#)

18:00 to 18:20

**Mauricio Schieda** (Institute of Materials Research, Helmholtz-Zentrum Geesthacht, Geesthacht, Germany), Herman Kriegel, Iris Herrmann-Geppert, Aafke C. Bronneberg, Deirdre L. Olynick, Thomas Klassen

[Solar Water Splitting With Nanoimprinted Model Photoelectrodes](#)

18:20 to 18:40

**Kenji Sakamaki** (Department of Chemistry, Fukushima College, National Institute of Technology, Iwaki, Japan), Ryoko Kato, Haruka Endo, Masataka Sato, Yoichi Kamo

[Photoelectrochemical Zero Bias Hydrogen Generation with a Novel Three Compartment Cell for Decreasing Theoretical and Total Water Electrolysis Voltage \(10\)](#)

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 201EF**

*Chaired by:* Chia-Ying Chiang, Daniel Scherson, Atsushi Iwanaga and YuYe Tong

14:00 to 14:20 Invited

**Denis Kramer** (Engineering Materials, University of Southampton, Southampton, United Kingdom), Tobias Binniger, Emiliana Fabbri, Thomas Justus Schmidt

[Theoretical Thoughts on Electronic Interactions between Metallic Electrocatalysts and Oxide Supports](#)

14:20 to 14:40

**Shuihua Tang** (School of Materials Science and Engineering, Southwest Petroleum University, Chengdu, China), Haixin Huangfu, Yuxiao Deng, Leping Sui, Zhen Dai, Zhentao Zhu, Xiaolong Qin, Jiawei Yuan

[High-Performance Electrocatalyst for Oxygen Reduction Derived from Riboflavin and Iron](#)

14:40 to 15:00

**Hiroyuki Koshikawa** (Department of Applied Chemistry, The University of Tokyo, Tokyo, Japan), Kazuhide Kamiya, Shuji Nakanishi, Kazuhito Hashimoto

[Heat-treated 3,5-diamino-1,2,4-triazole/graphene Hybrid Functions as an Oxygen Reduction Electrocatalyst with High Activity and Stability](#)

15:00 to 15:20

**Kotaro Sasaki** (Chemistry Department, Brookhaven National Laboratory, Upton, USA), Kurian Kuttijiel, Dong Su, Lijun Wu, Yimei Zhu, Radoslaw Adzic

[Gold-promoted structurally ordered intermetallic palladium cobalt nanoparticles for the oxygen reduction reaction](#)

15:20 to 15:40

**Ming Zhou** (Chemistry, The University of Hong Kong, Hong Kong, China), Kwong-Yu Chan

[Highly Active and Stable Iron-nitrogen-doped Carbon with Hollow-core-mesoporous-shell \(HCMS\) Structure for Oxygen Reduction Reaction](#)

15:40 to 16:00

**YuYe Tong** (Chemistry, Georgetown University, Washington, USA), Yanyan Wang

[Unexpected Good Deed of a Traditional Poison: Sulfur-Adsorption Enhanced Activity and Stability of Pt for Oxygen Reduction Reaction](#)

16:00 to 16:20

**Justus Masa** (Analytical Chemistry and Center for Electrochemical Sciences, Ruhr-Universitaet Bochum, Bochum, Germany), Wei Xia, Anqi Zhao, Martin Muhler, Wolfgang Schuhmann

[Electrocatalysis of oxygen reduction and water oxidation using metal oxides embedded in nitrogen-doped carbon](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Atsunori Ikezawa** (Graduate School of Engineering, Kyoto University, Kyoto, Japan), Kohei Miyazaki, Tomokazu Fukutsuka, Takeshi Abe

[Investigations of Triple Phase Boundary Regions in Bifunctional Air Electrodes Using Partially Immersed Platinum Electrodes](#)

17:00 to 17:20

**Samuel Perry** (Chemistry, University of Southampton, Southampton, United Kingdom), Guy Denuault

[Determination of Oxygen Binding Energy from Simple Amperometric Experiments and its Application Towards the Evaluation of Novel Materials for the Oxygen Reduction Reaction](#)

17:20 to 17:40

**Lior Elbaz** (Chemistry, Bar Ilan University, Ramat-Gan, Israel), Zeev Gross, Naomi Levi, Atif Mahammed

[Electroreduction of Oxygen with Brominated Metallo-Corroles](#)

17:40 to 18:00

**Claudio Zafferoni** (Department of Chemistry Ugo Schiff, University of Florence, Florence, Italy), Giulia Tuci, Giuliano Giambastiani, Massimo Innocenti

[Bimetallic catalysts and metal-free catalysts for ORR](#)

18:00 to 18:20

**Daniel Scherson** (Chemistry, Case Western Reserve University, Cleveland, USA), Adriel Jebaraj, Nicholas Georgescu

[On The Effects of Bromide Adsorption on the Rates of Redox Reactions](#)

18:20 to 18:40 Invited

**Minhua Shao** (Department of Chemical and Biomolecular Engineering, Hong Kong University of Science and Technology, Hong Kong, China)

[Size, Shape and Morphology Effects on Catalytic Activity of Oxygen Reduction Reaction](#)

## Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy

**Room : 101B**

*Chaired by:* Guohua Chen and Onofrio Scialdone

### 14:00 to 14:20 Invited **ISE Prize for Environmental Electrochemistry**

**Sergi Garcia-Segura** (Chemistry, Universidade Federal do Rio Grande do Norte, Natal, Brazil), Enric Brillas

[Electrochemical Processes Based on Fenton's Reaction for Wastewater Treatment. An Eco-Friendly, Efficient and Affordable Technology: Then, Now and Tomorrow](#)

### 14:20 to 14:40 Invited

**Ricardo Salazar** (Química de los Materiales, Universidad de Santiago de Chile, Santiago, Chile)

[Remediation of bovine slurry wastewater using electrochemical advances oxidation process.](#)

### 14:40 to 15:00

**Nelly Esther Flores Tapia** (Química Física, University of Barcelona, Barcelona, Spain), Enric Brillas, Ignacio Sirés, Pere Cabot, Rosa Rodríguez, José Garrido, Francisco Centellas

[Comparison of trans-cinnamic and trans-ferulic acids degradation by advanced oxidation processes](#)

### 15:00 to 15:20 Invited

**Ignacio González** (Universidad Autónoma Metropolitana-Iztapalapa, Chemistry, México, Mexico), Odín Rodríguez-Nava, Miguel Angel Arellano-González, Anne Claire Texier

[Removal of emerging pollutants and biodegradable organic matter from wastewater by combined electrochemical -biological processes](#)

### 15:20 to 15:40 Invited

**Bahadır K. Körbahti** (Mersin University, Chemical Engineering Department, Mersin University, Mersin, Turkey)

[Electrochemical Processes for Green Environment: the emerging technology in wastewater treatment](#)

### 15:40 to 16:00 Invited

**Minghua Zhou** (College of Environmental Science and Engineering, Nankai University, Tianjin, China), Liang Ma, Weilu Yang, Gengbo Ren, Fangke Yu

[Flow-through Electrochemical Cells for Efficient Dye Removal](#)

### 16:00 to 16:20

**Ali Farhat** (Advanced Water Management Centre, University of Queensland, Brisbane, Australia), Stephan Tait, Jurg Keller, Jelena Radjenovic

[Role of Sulfate and Persulfate Ions in Electrochemical Oxidation of Persistent Organics at a Boron-doped Diamond Anode](#)

### 16:20 to 16:40

Coffee Break

### 16:40 to 17:20 Keynote

**Yunny Meas** (Research and Development, CIDETEQ, Pedro Escobedo, Mexico), Alejandro Medel, Georgina Zuñiga, José A. Ramírez

[Novel Electrochemical Prototype for the Treatment of Spent Caustic from Hydrocarbon Industry and its Industrial Scaling](#)

### 17:20 to 17:40

**Konstantin Petrov** (Electrocatalysis, IEES-BAS, Sofia, Bulgaria), Venko Beshkov, Elena Razkazova, Djamal Uzun

[A method for the simultaneous cleansing of H<sub>2</sub>S and SO<sub>2</sub>](#)

### 17:40 to 18:00

**Hui-Wen Lin** (Advanced Water Management Centre, The University of Queensland, Brisbane, Australia), Korneel Rabaey, Jurg Keller, Zhiguo Yuan, Ilje Pikaar

[Simultaneous scaling-free electrochemical production of caustic and oxygen from domestic wastewater for sulfide control in sewers](#)

18:00 to 18:20

**Olivier Lefebvre** (Department of Civil and Environmental Engineering, National University of Singapore, Singapore, Singapore), Emmanuel Mousset, Muhammad Syafiq Bin Ahmad, Zuxin Wang

[Graphene-based electrodes: a new promising material for a more competitive electro-Fenton technology](#)

18:20 to 18:40

**Kenji Kawaguchi** (Organization for Research Initiatives and Development, Doshisha University, Kyo-tanabe, Kyoto, Japan), Masatsugu Morimitsu

[Reaction Selectivity of IrO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> Nano-Amorphous Hybrid Catalysts for Oxygen Evolution and Metal Oxide Deposition](#)

---

## Symposium 12: Physical Electrochemistry: Spectroscopic, Structural, and Theoretical Investigations of the Electrified Interface

---

**Room : 101C**

*Chaired by:* Hirohito Ogasawara, Kelsey A. Stoerzinger and Juan M. Feliu

14:00 to 14:40 Keynote

**Hirohito Ogasawara** (2SUNCAT ctr for Interface Science and Catalysis, SLAC National Accelerator Laboratory, Menlo Park, USA), Daniel Friebe, Anders Nilsson

[Operando X-ray Studies of Electrocatalysis](#)

14:40 to 15:00 Invited

**Kelsey A. Stoerzinger** (Department of Materials Science & Engineering, Massachusetts Institute of Technology, Cambridge, USA), Wesley T. Hong, Yueh-Lin Lee, Livia Giordano, Yang Shao-Horn

[Molecular Insight into Wetted Oxide Surfaces and Oxygen Electrocatalysis](#)

15:00 to 15:20 Invited

**Ryosuke Jinnouchi** (Material Design Lab., Toyota Central R&D Labs., Inc., Nagakute, Japan), Kensaku Kodama, Eishiro Toyoda, Kenji Kudo, Naoki Kitano, Naoki Hasegawa, Yu Morimoto

[Atomistic Simulations for Designing High-Performance Electrode Materials for Polymer Electrolyte Fuel Cells](#)

15:20 to 15:40

**Andy Wain** (Materials Division, National Physical Laboratory, Teddington, United Kingdom)

[Mapping Oxygen Reduction at Individual Nanostructures Using High-Resolution Electrochemical-Topographical Imaging](#)

15:40 to 16:00

**Marta Figueiredo** (Leiden Institute of Chemistry, Leiden University, Leiden, Netherlands), Marc T.M. Koper

[CO<sub>2</sub> electroreduction products and intermediates in organic solvents](#)

16:00 to 16:20

**Sunny Hy** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Felix Felix, Bing-Joe Hwang

[Designing In Situ Solid Electrolyte Interphase Studies using Surface-enhanced Raman Spectroscopy](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Zhong-Qun Tian** (Chemistry Department, Xiamen University, Xiamen, China), Meng Zhang, William Valenzuela, Runwen Yan, Songyuan Ding, Juan Perez, De-Yin Wu, Bingwei Mao, Juan M. Feliu,

[Extending Shell-isolated Nanoparticle-enhanced Raman Spectroscopy to Study Ordered/Disordered](#)

[Adsorption of \(Bi\)sulfate on Au Single Crystal Electrodes](#)

17:00 to 17:20

**Masato Tominaga** (Graduate School of Science and Technology, Kumamoto University, Kumamoto, Japan), Yudai Nagahama, Yuto Yatsugi[Raman Spectroscopic Detection of Electrochemical Oxidative Reaction of Single-Walled Carbon Nanotubes](#)

17:20 to 17:40

**Shino Sato** (Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo, Japan), Kohei Uosaki, Kei Murakoshi, Katsuyoshi Ikeda[Interface control in a chemically modified electrode for overpotential reduction](#)

17:40 to 18:00

**Juan M. Feliu** (Physical Chemistry, University of Alicante, Alicante, Spain), Paula Sebastian, Ricardo Martinez-Hincapie, Andrea Sandoval, Victor Climent[Laser induced temperature jump investigation of the interface between Pt single crystals in contact with ionic liquids](#)

18:00 to 18:20

**Robert Hillman** (Department of Chemistry, University of Leicester, Leicester, United Kingdom), Rachel Sapstead, Virginia Ferreira, Karen Smith, Karl S. Ryder, Emma Smith, Nina-Juliane Steinke, Robert Dalglish[Dynamic In Situ Neutron Reflectivity Studies of Metal Electrodeposition and Alloy Formation in Ionic Liquid Media](#)

18:20 to 18:40

**Kenta Motobayashi** (Catalysis Research Center, Hokkaido University, Sapporo, Japan), Kazuya Minami, Ken-ichi Uchida, Naoya Nishi, Tetsuo Sakka, Masatoshi Osawa[Potential-Dependent Behavior of Ionic Liquid \[BMIM\]\[TfSA\] with Additives on a Gold Electrode Studied by Surface-Enhanced Infrared Absorption Spectroscopy](#)

---

## Symposium 16: Supramolecular Electrochemistry for Analysis, Medicine and Biological Sciences

---

**Room : 201D***Chaired by:* Stephane Arbault and Olivier Buriez

14:00 to 14:40 Keynote

**Richard McCreery** (Department of Chemistry, University of Alberta, Edmonton, Canada), Adam Bergren, Nikola Pekas, Oleksii Ivanshenko, Jerry Fereiro, Bryan Szeto[Charge Transport Through Molecules Acting as “Supramolecular” Electronic Devices](#)

14:40 to 15:00

**Ping Yu** (Institute of Chemistry, Chinese Academy of Sciences, Beijing, China), Lanqun Mao[Imidazolium-Based Supramolecular Ionic Material and Its Application in Biosensing and Electronic Device](#)

15:00 to 15:20 Invited

**Serge Cosnier** (Department of Molecular Chemistry, Grenoble Alpes University-CNRS, Grenoble, France)[Supramolecular Biological Assemblies for Biosensors and Biofuel Cells](#)

15:20 to 15:40

**Pawel Kryszinski** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Dorota Nieciecka, Aleksandra Joniec[Magnetic Nanoparticles and Magnetoliposomes as Anticancer Drug Carriers](#)

15:40 to 16:00

**Dorota Matyszewska** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Renata Bilewicz, Jan Biernat[Interactions of Anticancer Drug and Adducts of the Drug with Carbon Nanotubes with Model Biological Membranes – Langmuir-Blodgett and Electrochemical Studies](#)

16:00 to 16:20 Invited

**Lars Jeuken** (School of Biomedical Sciences, University of Leeds, Leeds, United Kingdom)

[Lipid-Membrane Modified Electrodes to Study Respiratory Membrane Enzymes and their Complexes in a Native-Like Lipid Environment](#)

16:20 to 16:40

Coffee Break

16:40 to 17:20 Keynote

**Richard Compton** (Chemistry, Oxford University, Oxford, United Kingdom)

[Nano Impacts: Recent Advances](#)

17:20 to 17:40

**Enno Kätelhön** (Department of Chemistry, Physical and Theoretical Chemistry, University of Oxford, Oxford, United Kingdom), Shaltiel Eloul, Christopher Batchelor-McAuley, Kristina Tschulik, Richard Compton

[First-Passage Statistics in Nanoelectrochemistry: Applications to Nano-Impacts](#)

17:40 to 18:00 Invited

**Marcin Opallo** (Department of Electrode Processes, Institute of Physical Chemistry Polish Academy of Sciences, Warszawa, Poland), Joanna Dolinska, Palanisamy Kannan, Volodymyr Sashuk, Janusz Sobczak, Zbigniew Kaszkur, Wojciech Lisowski, Martin Jonsson Niedziolka

[Electrocatalytic glucose oxidation in suspension and film consisting charged Au and Pt nanoparticles](#)

18:00 to 18:20

**Hua Cui** (Department of Chemistry, University of Science and Technology of China, Hefei, China), Hongli Zhang, Zhili Han

[One-step Supermolecule Assembly of N-\(aminobutyl\)-N-\(ethylisoluminol\) Functionalized Gold Nanodots on Multiwalled Carbon Nanotubes and Their Applications to Sensors](#)

18:20 to 18:40

**Fred Lisdat** (Biosystems Technology, Institute of Applied Life Sciences, Technical University Wildau, Wildau, Germany), S. Feifel, R. McGovern, P. Crowley, Roland Ludwig

[Artificial protein architectures on electrodes](#)

---

## Symposium 17: Novel in Situ in Operando Methods

---

**Room : 103**

*Chaired by:* Fu-Ming Wang and Patrick Unwin

14:00 to 14:40 Keynote

**Karl Mayrhofer** (Department of Interface Chemistry and Surface Engineering, Max-Planck-Institut for Iron Research, Düsseldorf, Germany), Serhiy Cherevko, Jan-Philip Grote, Chang-Hyuck Choi, Aleksandar Zeradjanin, Nejc Hodnik, Claudio Baldizzone, Simon Geiger

[In-situ investigation of catalyst degradation](#)

14:40 to 15:00

**Bin Ren** (Department of Chemistry, Xiamen University, Xiamen, China), Cheng Zong, Chanjuan Chen, Meng Zhang

[Electrochemical Surface-Enhanced Raman Microscopy \(EC-SERM\)](#)

15:00 to 15:20

**Sandra Rondinini** (Department of Chemistry, Università degli Studi di Milano, Milano, Italy), Paolo Ghigna, Elisabetta Achilli, Alberto Vertova, Cristina Locatelli, Francesco D'Acapito

[Combined Ionic Diffusion and Faradaic Reactions in Electrodeposited Highly Hydrated Amorphous Iridium Oxide by in-operando Dispersive XAS Investigation](#)

15:20 to 15:40

**Eric Sorte** (Department of Chemistry, Georgetown University, Washington DC, USA), YuYe Tong[Innovations in In situ Electrochemical Nuclear Magnetic Resonance](#)

15:40 to 16:00

**Sarah Day** (Diamond Light Source, Diamond Light Source, Didcot, United Kingdom), Annabelle Baker, Chiu Tang[A Long Duration Experiment Facility for the Study of Battery Materials Using In Situ Synchrotron X-Ray Powder Diffraction](#)

16:00 to 16:20

**Simon Thiele** (Institute of Microsystems Engineering (IMTEK), University of Freiburg, Freiburg, Germany)[Multi-scale tomographic analysis of fuel cells, batteries and electrolyzers](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Mario El Kazzi** (Electrochemical Energy Storage Section (PSI), Paul Scherrer Institut (PSI), Villigen, Switzerland), Daniel Streich, Petr Novak[Complementary Operando XPS and Raman Spectroscopy of Ggraphite Cycled in Ionic Liquids](#)

17:00 to 17:20

**Misun Hong** (Byon Initiative Research Unit (IRU), RIKEN, Wako, Japan), Hee Cheul Choi, Hye Ryung Byon[In Situ Visualization of  \$\text{Li}\_2\text{O}\_2\$  Decomposition for a  \$\text{Li}-\text{O}\_2\$  Battery Using Electrochemical Atomic Force Microscopy \(ECAFM\)](#)

17:20 to 17:40

**Yoshiharu Uchimoto** (Graduate School of Human and Environmental Studies, Kyoto University, Kyoto, Japan), Yuki Orikasa[Operando synchrotron X-ray analysis for investigation of electrode property of lithium ion battery cathode](#)

17:40 to 18:00

**Neeraj Sharma** (School of Chemistry, UNSW Australia, Sydney, Australia)[The time and current-resolved evolution of sodium location and distribution in electrodes of sodium-ion batteries](#)

18:00 to 18:40 Keynote

**Hector Abruña** (Chemistry and Chemical Biology, Cornell University, Ithaca, USA)[Operando Methods for the Characterization Energy Materials](#)

# Tuesday, 6 October 2015 - Morning

---

## Plenary Lecture

**Room : Plenary Hall**

*Chaired by:* Bing Joe Hwang

08:15 to 09:15

**Hongjie Dai** (Stanford University, Stanford, USA)

[Novel Materials for Renewable Energy](#)

---

## Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications

**Room : 101D**

*Chaired by:* Sofiene Abdellaoui and Vera Essmann

09:30 to 09:50

**Dechen Jiang** (School of Chemistry and Chemical Engineering, Nanjing University, Nanjing, China)

[Luminol Electrochemical-luminescence for Single Cell Analysis](#)

09:50 to 10:10

**Tomoyuki Yasukawa** (Graduate School of Material Science, University of Hyogo, Ako, Japan), Yuki Minakuchi, Hironobu Hatanaka, Fumio Mizutani

[Negative dielectrophoretic separation of cells based on the expression of specific surface antigen](#)

10:10 to 10:50 Keynote

**Christine Kranz** (Institute of Analytical and Bioanalytical Chemistry, University of Ulm, Ulm, Germany), Corinna Frey, Alexander Eifert, Holger Barth, Boris Mizaikoff

[Investigation of pore forming proteins in supported lipid membranes](#)

10:50 to 11:10

Coffee Break

## Symposium 3: Batteries for Tomorrow's World

Room : 201AB

Chaired by: Atsuo Yamada

09:30 to 10:10 Keynote

**George Crabtree** (Joint Center for Energy Storage Research (JCESR), Argonne National Laboratory, Argonne, USA)

[The Joint Center for Energy Storage Research \(JCESR\): A New Paradigm for Energy Storage Research](#)

10:10 to 10:30 Invited **Hans-Jürgen Engell Prize**

**Fabio La Mantia** (Analytical Chemistry, Ruhr-Universität Bochum, Bochum, Germany)

[Aqueous Zinc-Ion Batteries based on Prussian Blue Derivatives](#)

10:30 to 10:50

**Yuping Wu** (College of Energy, Nanjing Tech University, Nanjing, China), Zheng Chang, Yanfang Wang

[New Concept Aqueous Rechargeable Batteries with High Energy Densities](#)

10:50 to 11:10

Coffee Break

## Symposium 4: Advances in Fuel Cells from Materials to Systems

Room : 102

Chaired by: Hiroyuki Uchida

09:30 to 10:10 Keynote

**Swami Kumaraguru** (Fuel Cell Activities, General Motors, Pontiac, USA), Jingxin Zhang, Wenbin Gu, Balsu Lakshmanan, Mark Mathias

[PEMFC Cathode Performance and Durability Challenges at Low Platinum Loading](#)

10:10 to 10:30

**Alexandra Patru** (Electrochemistry Laboratory, Paul Scherrer Institut, Villigen, Switzerland), Johannes Biesdorf, Antoni Forner Cuenca, Emiliana Fabbri, Pierre Boillat, Thomas Justus Schmidt

[Performance and Stability of New Oxide Catalyst Supports under PEFC Operating Conditions](#)

10:30 to 10:50

**Maxi Frei** (IMTEK, Department of Microsystems Engineering, University of Freiburg, Freiburg, Germany), Johannes Erben

[Fabrication of platinum electrodes with high roughness factor using a 3D-support](#)

10:50 to 11:10

Coffee Break

---

## Symposium 5: Novel Insights to Electrochemical Capacitors

---

**Room : 101A**

*Chaired by:* Masashi Ishikawa

09:30 to 10:10 Keynote

**Kwang-Bum Kim** (Department of Material Science and Engineering, Yonsei University, Seoul, Korea), Sang-Hoon Park, Hyun-Kyung Kim, Hee Chang Youn, Myeong-Seong Kim, Suk-Woo Lee

[Graphene-based Nanomaterials for Energy Storage Devices](#)

10:10 to 10:30

**Dominic Rochefort** (Chemistry, Universite de Montreal, Montreal, Canada), Han Jin Xie, Bruno Gelinas

[On the Performance and Self-Discharge of a Redox-Active Electrolyte Supercapacitor Based on an Ionic Liquid Modified with Ferrocene](#)

10:30 to 10:50

**Tavo Romann** (Institute of Chemistry, University of Tartu, Tartu, Estonia), Erik Anderson, Ove Oll, Piret Pikma, Enn Lust

[High Voltage Graphene Capacitor Technology](#)

10:50 to 11:10

Coffee Break

---

## Symposium 6: New Progress in Electrochemical Solar Cells

---

**Room : 201C**

*Chaired by:* Peter Deák

09:30 to 09:50 Invited

**Ib Chorkendorff** (Department of Physics, Technical University of Denmark, Kongen Lyngby, Denmark)

[The Challenge of Interfacing Catalysts, Protection layers, and Semiconductors in a Tandem Device](#)

09:50 to 10:10 Invited

**Kuei-Hsien Chen** (IAMS, Academia Sinica, Taipei, Taiwan)

[Graphene Oxides Based Photocatalyst for Solar Fuels](#)

10:10 to 10:30

**Marcel Schreier** (Institute of Chemical Sciences and Engineering, Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland), T. M. Aufar Kari, Laura Curvat, Thomas Moehl, Fabrizio Giordano, Antonio Abate, Jingshan Luo, Matthew T. Mayer, Michael Grätzel

[Efficient sunlight-driven reduction of CO<sub>2</sub> to fuels based on Cu<sub>2</sub>O and perovskite absorbers](#)

10:30 to 10:50

**Yi-June Huang** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Miao-Syuan Fan, Chun-Ting Li, Chuan-Pei Lee, R. Vittal, Kuo-Chuan Ho

[A Low<sub>i</sub> VCost Counter Electrode with a MoSe<sub>2</sub>/PEDOT:PSS Composite Catalytic Film for Dye-Sensitized Solar Cells](#)

10:50 to 11:10

Coffee Break

## Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication

**Room : 103**

*Chaired by:* Stanko Brankovic and Natasa Vasiljevic

09:30 to 10:10 Keynote

**Nikolay Dimitrov** (Chemistry, Binghamton University - SUNY, Binghamton, USA)

[Advances in the Growth of Metals and Alloys Assisted by a Monolayer Amount of UPD Atoms](#)

10:10 to 10:30 Invited

**Natasa Vasiljevic** (School of Physics, University of Bristol, Bristol, United Kingdom), Benjamin Rawlings, Michael P. Mercer, Zakiya Al Amri

[Surface Limited Redox Replacement Design of Pt Bimetallic Nanostructures](#)

10:30 to 10:50 Invited

**Stanko Brankovic** (Electrical and Computer Engineering, University of Houston, Houston, USA), Ela Bulut, Donjun Wu, Hasan Kilic

[SLRR of UPD Monolayers – Fundamental Aspects and Interplay of UPD, Reaction Kinetics, and Nucleation](#)

10:50 to 11:10

Coffee Break

## Symposium 9: Electrocatalytic Materials

**Room : 201EF**

*Chaired by:* Chen-Hao Wang

09:30 to 10:10 Keynote

**Jong-Sung Yu** (Department of Energy Systems Engineering, Daegu Gyeongbuk Institute of Science and technology (DGIST), Daegu, Korea), Dea-Soo Yang, Min Young Song, Kiran Pal Singh, Fatemeh Razmjooei  
Heteroatom-Doped Porous Carbon as Electrocatalyst: Surface Properties and Electrocatalytic Activity

10:10 to 10:30

**Candice Rassie** (Chemistry, University of the Western Cape, Cape Town, South Africa), Lindsay Wilson, Priscilla Baker, Emmanuel Iwuoha

[Microscopic and Electrochemical Signatures of Copper-poly\(propyleneimine\) Metallodendrimer System](#)

10:30 to 10:50

**Yan-Xia Jiang** (Department of Chemistry, Xiamen University, Xiamen, China), Bin-Wei Zhang, Shi-Gang Sun

[Pt<sub>3</sub>Ni intermetallic with Pt-rich surface supported on porous carbon as a high efficient electrocatalyst for oxygen reduction reaction](#)

10:50 to 11:10

Coffee Break

---

## Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy

---

**Room : 101B**

*Chaired by:* Juan Manuel Peralta-Hernández and Carlos Ponce de Leon

09:30 to 10:10 Keynote

**Geoff Kelsall** (Department of Chemical Engineering, Imperial College London, London, United Kingdom), Nick Farandos, Anna Hankin, Lisa Kleiminger

[Electrode Structural Effects on Solid Oxide Electrolyser Performance](#)

10:10 to 10:30

**Antonio de Lucas Consuegra** (Chemical Engineering, Castilla La Mancha, Ciudad Real, Spain), Jesús Gonzalez-Cobos, Victor Rico, Agustín Gonzalez-Elipe, Jose Luis Valverde

[Hydrogen production and storage by coupling of catalysis and electrochemistry](#)

10:30 to 10:50

**Jesus Iniesta** (Physical Chemistry and Institute of Electrochemistry, Alicante University, Alicante, Spain), Leticia Garcia-Cruz, Vicente Montiel, Conchi Ania

[Electrocatalytic properties of Cu-/Ni-loaded nanoporous carbons for the electrooxidation of alcohols](#)

10:50 to 11:10

Coffee Break

---

## Symposium 12: Physical Electrochemistry: Spectroscopic, Structural, and Theoretical Investigations of the Electrified Interface

---

**Room : 101C**

*Chaired by:* Aliaksandr Bandarenka and Ana Sofia Varela

09:30 to 09:50

**Enrique Herrero** (Instituto de Electroquímica, Universidad de Alicante, Alicante, Spain), Valentin Briega-Martos, Adolfo Ferre-Vilaplana

[Effect of Acetonitrile Adsorption on the ORR on Platinum Single Crystal Electrodes. A Combined Electrochemical, Spectroscopic and DFT Study](#)

09:50 to 10:10

**Ioannis Katsounaros** (Leiden Institute of Chemistry, Leiden Universiteit, Leiden, Netherlands), Pietro P. Lopes, Dusan Strmcnik, Andrew Gewirth, Marc T.M. Koper, Nenad M. Markovic

[Electrochemical Oxidation of Ammonia on Pt\(100\) in Alkaline Solutions](#)

10:10 to 10:30

**Jian-Feng Li** (Chemistry, Xiamen University, Xiamen, China), Chao-Yu Li, Jin-Chao Dong, Xi Jin

[Electrochemical Shell-Isolated Nanoparticle-Enhanced Raman Spectroscopy \(EC-SHINERS\)](#)

10:30 to 10:50

**Azhagurajan Mukkannan** (Frontier Institute for Interdisciplinary Sciences, Tohoku University, Sendai, Japan), Takashi Itoh

[Direct observation of electrochemical processes at single atomic layer: an advanced optical microscopy study](#)

10:50 to 11:10

Coffee Break

## Symposium 15: Electrochemical Engineering from a Quantum Description to the Plant Modeling: Experiments and Design across Length Scale

**Room : South Lounge**

*Chaired by:* Alejandro A. Franco

09:30 to 09:50 Invited

**Frédéric Sauvage** (Laboratoire de Réactivité et Chimie des Solides, CNRSUMR7314, Université de Picardie Jules Verne, Amiens, France)

[Solid electrolyte interphase formation in dye-sensitized solar cells: where experimental ends and modeling could start](#)

09:50 to 10:10 Invited

**Hye Jin Lee** (Chemistry, Kyungpook National University, Daegu, Korea)

[Electrochemistry with Nanobioconjugates and Soft Interfaces for Sensing Applications](#)

10:10 to 10:30

**Fadhila Sekli Belaidi** (Micro-Nano-Bio-Technologie, LAAS-CNRS, Toulouse, France), William Tiddi, Matthieu Polverel, Gabriel Lemercier, Venkata Suresh Reddy Vajrala, Dodzi Zigah, Neso Sojic, Jérôme Launay, Pierre Temple-Boyer, Stephane Arbault

[Arrays of Microwells Equipped with a Recessed Ring Nanoelectrode and a Disk Microelectrode for Nanoelectrochemistry Investigations](#)

10:30 to 10:50

**Ivan Kondov** (Steinbuch Centre for Computing, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany), Patrick Faubert, Claas Müller, Holger Reinecke

[Modelling, Simulation and Characterization of Electrocatalytic Oxygen Reduction on Cr-modified Ni Surfaces](#)

10:50 to 11:10

Coffee Break

## Symposium 16: Supramolecular Electrochemistry for Analysis, Medicine and Biological Sciences

**Room : 201D**

*Chaired by:* Chii-Wann Lin and Francesco Paolucci

09:30 to 09:50

**Renata Bilewicz** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Ewa Nazaruk, Monika Szlezak, Ehud M. Landau

[Lyotropic cubic phase gels and nanoparticles for drug delivery: tuning drug diffusion and sustained release from the mesophase](#)

09:50 to 10:10

**Olga Swiech** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Ewelina Kurowicka, Agata Krzak, Maciej Majdecki, Marcin Kruszewski, Renata Bilewicz

[Application of New Conjugate of Cyclodextrin and Lipoic Acid in pH-Sensitive, Multifunctional Drug Carriers](#)

10:10 to 10:50 Keynote

**Alexander Kuhn** (ENSCBP, University Bordeaux, Pessac, France), Thittaya Yutthalekha, Chularat Wattanakit, Yémima Bon Saint Côme, Veronique Lapeyre, Philippe A. Bopp, Matthias Heim, Sudarat Yadnum, Somkiat Nokbin, Chompunuch Warakulwit, Jumras Limtrakul

[Supramolecular Enantioselective Recognition at Mesoporous Chiral Metal Surfaces](#)

10:50 to 11:10

Coffee Break

# Tuesday, 6 October 2015 - Afternoon

## Symposium 1: New Directions in Analytical Electrochemistry

Room : 103

Chaired by: J. Justin Gooding; Yi-Tao Long

### 14:00 to 14:40 Keynote

**Osamu Niwa** (Biomedical Research Institute, National Institute of Advanced Industrial Sci. and Tech., Tsukuba, Japan), Dai Kato, Tomoyuki Kamata, Daiki Kato, Shunsuke Shiba, Shigeru Hirono, Eisuke Kuraya, Masashi Kunitake, Naoto Yamaguchi, Hiroshi Imaya

[Hybrid carbon film electrodes for electroanalytical applications](#)

### 14:40 to 15:00

**Andreas Lesch** (Laboratory of Physical and Analytical Electrochemistry, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland), Fernando Cortés-Salazar, Sunny Maye, Véronique Amstutz, Philippe Tacchini, Hubert Girault

[Nano-Hydrogel Modified Carbon Nanotubes Electrodes for Antioxidant Monitoring in Complex Samples](#)

### 15:00 to 15:20

**Shaneel Chandra** (School of Biological and Chemical Sciences, The University of the South Pacific, Suva, Fidji), Wycliff Tupiti

[Gold nanoparticles-modified physically small carbon sensors towards sensitive and selective As\(III\) detection in aquatic samples](#)

### 15:20 to 15:40

**Salvatore Daniele** (Molecular Sciences and Nanosystems, University Cà Foscari Venice, Venice, Italy), Alberto Citron, Dario Battistel, Carlo Bragato, Daniele Veclani

[Disk Shaped Platinum Nanoelectrodes with Unexpected High Surface Area for the Detection of Hydrogen Peroxide](#)

### 15:40 to 16:00

**Yukihiro Shintani** (School of Science and Engineering, Waseda University, Tokyo, Japan)

[All-solid-State pH Sensor utilizing Termination-controlled Boron-doped Diamond Surface as pH-sensitive/pH-less-sensitive Interface](#)

### 16:20 to 16:40

Coffee Break

### 16:40 to 17:00 Invited

**Jyh-Myng Zen** (Chemistry, National Chung Hsing University, Taichung, Taiwan)

[An Easily Applicable Green Method for Real Sample Analysis Based on Disposable Gas Sensor](#)

### 17:00 to 17:20

**Grzegorz Lisak** (Chemical Engineering, Process Chemistry Centre, Laboratory of Analytical Chemistry, Åbo Akademi, Åbo-Turku, Finland), Jingwen Cui, Sylwia Strzałkowska, Thomas Arnebrant, Tautgirdas Ruzgas, Johan Bobacka

[Analytical Applications of Paper and Textiles in Microfluidic Sampling and Sample Handling Integrated with Electrochemical Sensors](#)

### 17:20 to 17:40

**Christopher Brett** (Department of Chemistry, University of Coimbra, Coimbra, Portugal), Madalina M. Barsan, Melinda David, Monica Florescu

[Self-Assembled Layer-by-Layer Architectures for Electrochemical Sensors and Biosensors](#)

17:40 to 18:00

**Christian Andre Gunawan** (School of Chemistry, The University of New South Wales, Sydney, Australia),  
Richard Gondosiswanto, Mengchen Ge, Chuan Zhao

[Salt-on-a-chip: Miniaturized Ionic Liquid Systems](#)

18:00 to 18:20

**Mario Castaño-Álvarez** (R&D, Micrux Technologies, Oviedo, Spain), Ana Fernández-la-Villa, Diego F. Pozo-Ayuso, Jorge Elizalde, María Tijero

[Novel Microfluidic Electrochemical Sensors for Thin-Layer based Flow Analysis Systems](#)

TUESDAY PM

## Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications

**Room : 101D**

*Chaired by:* Damien Arrigan and Ross Milton

14:00 to 14:40 Keynote

**Lanqun Mao** (Institute of Chemistry, Chinese Academy of Sciences, Beijing, China)

[Enabling Bioelectrochemistry for In Vivo Analysis](#)

14:40 to 15:00

**Shen-Ming Chen** (Department of Chemical Engineering and Biotechnology, National Taipei University of Technology, Taiwan), Chelladurai Karuppiah, Rajkumar Devasenathipathy, Selvakumar Palanisamy, Verappan Mani

[Synthesis and Characterization of carbon based nanocomposites and its electrocatalytic activity towards biomolecules and hazardous pollutants](#)

15:00 to 15:20

**Nicolas Mano** (CRPP- UPR 8641, Bordeaux, Pessac, France), Anne Sophie Michardière, Cintia Mateo-Mateo, Sébastien Gounel, Isabelle Ly, Philippe Poulin

[Wet spun Bio-electronic fibers of imbricated enzymes and carbon nanotubes for efficient microelectrodes](#)

15:20 to 15:40

**Stéphane Arbault** (Institute of Molecular Sciences - CNRS, University of Bordeaux, PESSAC, France), Emmanuel Suraniti, Salem Ben-Amor, Pauline Landry, Michel Rigoulet, Eric Fontaine, Serge Bottari, Anne Devin, Neso Sojic, Nicolas Mano

[Monitoring Electrochemically the Early Events of Hydrogen Peroxide Production by Mitochondria](#)

15:40 to 16:00

**Libuse Trnkova** (Department of Chemistry, Faculty of Science, Masaryk University, Brno, Czech Republic), Iveta Pilarova

[DNA Heptamers with Different Central Trinucleotide Sequences Studied by Electrochemical and Spectral Methods](#)

16:00 to 16:20

**Ana Maria Oliveira-Brett** (Chemistry Department, University of Coimbra, University of Coimbra, Coimbra, Portugal), A.M. Chiorcea-Paquim, T.A. Enache

[Amyloid  \$\beta\$  Peptides Nanostructures: Voltammetric and Atomic Force Microscopy Characterization](#)

16:20 to 16:40

Coffee Break

16:40 to 16:50

**Alexandra Bondarenko** (Institut des sciences et ingénierie chimiques, Ecole polytechnique fédérale de Lausanne, Lausanne, Switzerland), Tzu-En Lin, Horst Pick, Andreas Lesch, Fernando Cortés-Salazar, Hubert Girault

[Scanning electrochemical microscopy of adherent melanoma cells: alive, fixed and permeabilized](#)

16:50 to 17:00

**Daliborka Jambrec** (Analytical Chemistry - Center for Electrochemical Sciences, Ruhr University Bochum, Bochum, Germany), Magdalena Gebala, Fabio La Mantia, Wolfgang Schuhmann

[Diving into the Mechanism of Potential-Assisted ssDNA Immobilization](#)

17:00 to 17:10

**Vera Essmann** (Analytical Chemistry - Center for Electrochemical Science, Ruhr-Universität Bochum, Bochum, Germany), Yasin Ugur Kayran, Daliborka Jambrec, Adrian Ruff, Stefanie Grützke, Wolfgang Schuhmann

[Facile optimization of gold nanostructures for high SERS intensity by means of bipolar electrochemistry](#)

17:10 to 17:20

**Karen Monsalve** (Bioenergetics and Protein Engineering, Mediterranean Institute of Microbiology-CNRS, Marseille, France), Alan Le Goff, Nicolas Mano, Cristina Gutierrez-Sanchez, Jean-Yves Lojou, Elisabeth Lojou

[H<sub>2</sub>/O<sub>2</sub> Biofuel Cells: Macro-structured Conductive Supports to Enhance Power Cell Performances](#)

17:20 to 17:30

**Shajahan Siraj** (Department of Chemistry and Biomolecular Sciences, Macquarie University, Sydney, Australia)

[Hydrogenated and 4-Sulfobenzene Modified Conical-tip Carbon Electrodes with Antifouling Property for Sensitive Detection of Dopamine](#)

17:30 to 17:40

**Bongkyu Kim** (School of Environmental Science and Engineering, Gwangju Institute of Science and Technology, Gwangju, Korea), Yooseok Lee, Jisu Kim, In Seop Chang

[Commercialization Strategies of Microbial Fuel Cells: Prevention of Voltage reversal in Stackable Approach](#)

17:40 to 17:50

**Rachel Gao** (Chemistry, University of Southampton, Southampton, United Kingdom), Sarah A. Goodchild, Philip Bartlett

[Anthraquinone Labelled DNA for Direct Detection and Discrimination of Closely Related DNA Targets](#)

17:50 to 18:00

**Chun-Hao Su** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Chung-Wei Kung, Kuo-Chuan Ho, Ying-Chih Liao

[Fabrication of Uniform Metal-organic Framework Thin Film via Inkjet Printing Technology and its Application as a Nitrite Sensor](#)

18:00 to 18:10

**Yung-Chun Lin** (Chemistry, University of Southampton, Southampton, United Kingdom), James Richardson, Tom Brown, Philip Bartlett

[Surface-Enhanced Raman Spectroscopic study of a DNA Beacon Probe Immobilized at a Au Electrode](#)

18:10 to 18:20

**Xiaochun Tian** (College of Chemistry & Chemical Engineering, Xiamen University, Xiamen, China), Ranran Wu, Zhiyong Zheng, Feng Zhao, Yan-Xia Jiang, Shi-Gang Sun

[Electron Transfer effect on the Bioluminescence of Shewanella Woodyi](#)

18:20 to 18:30

**Makoto Togami** (Graduate School of Science and Technology, Kumamoto University, Kumamoto, Japan), Aiko Sasaki, Masato Tominaga

[Acceleration of Laccase Bioelectrocatalysis at Carbon Nanotube Interface Modified with Steroid-Type Biosurfactants](#)

## Symposium 3: Batteries for Tomorrow's World

Room : 201AB

Chaired by: Minoru Inaba

14:00 to 14:20 Invited

**Takeshi Abe** (Graduate School of Engineering, Kyoto University, Kyoto, Japan), Shohei Maruyama, Kohei Miyazaki

[Rate Determining Factors at Graphite Electrodes- from charge transfer resistances to ion transport resistances -](#)

14:20 to 14:40 Invited

**M. V. Reddy** (Materials Science & Engg and Physics, National University of Singapore, Singapore, Singapore)

[Novel V-containing cathode materials for Li-ion Batteries](#)

14:40 to 15:00

**Shuji Ding** (Department of Applied Chemistry, Xi'an Jiaotong University, Xi'an, China)

[The Design and Preparation of Multi-dimensional Nanostructured Materials and electrochemical storage](#)

15:00 to 15:20

**Alejandro A. Franco** (Laboratoire de Réactivité et Chimie de Solides (LRCS), Université de Picardie Jules Verne & CNRS, Amiens, France), Garima Shukla, Matias A. Quiroga, Kan-Hao Xue, Trong-Khoa Nguyen, Guillaume Blanquer, Yinghui Yin

[Computational data mining to boost the next generation batteries R&D: the composite electrode architecture](#)

15:20 to 15:40

**Andrzej Lewandowski** (Faculty of Chemical Technology, Poznan University of Technology, Poznan, Poland)

[Li-ion battery operation limits](#)

15:40 to 16:00

**Alexandre Ponrouch** (QES, ICMAB-CSIC, Bellaterra, Spain), Carlos Frontera, Fanny Bardé, M. Rosa Palacín

[Towards a rechargeable battery technology based on calcium](#)

16:00 to 16:20

**Kolja Beltrop** (MEET Battery Research Centre, WWU, University of Münster, Münster, Germany), Martin Winter, Tobias Placke

[Does Size really Matter? New Insights into the Intercalation Behavior of Anions into a Graphite Based Positive Electrode](#)

16:20 to 16:40

Coffee Break

16:40 to 17:20 Keynote

**Atsuo Yamada** (Department of Chemical System Engineering, The University of Tokyo, Tokyo, Japan), Masashi Okubo, Prabeer Barpanda, Shin-ichi Nishimura, Sai-Cheong Chung, Gosuke Oyama, Yuya Suzuki

[Alluaudite  \$\text{Na}\_{2+2x}\text{Fe}\_{2-x}\(\text{SO}\_4\)\_3\$  as 3.8 V Sodium Battery Cathode](#)

17:20 to 17:40 Invited

**Shirley Meng** (Sustainable Power and Energy Center, University of California San Diego, La Jolla, USA), Chuze Ma, Judith Alvarado, Jing Xu, Haodong Liu

[Designing and optimizing novel electrode materials for rechargeable Na-ion batteries with high energy and low cost](#)

17:40 to 18:00

**Jie Li** (MEET Battery Research Center/Institute of Physical Chemistry, University of Muenster, Muenster, Germany), Jun Wang, Xin He, Haidong Liu, Tim Risthaus, Tim Risthaus

[Synthesis and electrochemistry performance of  \$\text{Na}\[\text{FeTi}\]\text{O}\_4\$  as anode material for sodium-ion batteries](#)

18:00 to 18:20

**Ha-Kyung Roh** (Department of Material Science and Engineering, Yonsei University, Seoul, Korea), Hyun-Kyung Kim, Myeong-Seong Kim, Kwang Chul Roh

[One-pot synthesis of NaTi<sub>2</sub>\(PO<sub>4</sub>\)<sub>3</sub>/rGO nanocomposite for sodium-ion batteries](#)

18:20 to 18:40

**Masashi Okubo** (Department of Chemical System Engineering, The University of Tokyo, Tokyo, Japan), Satoshi Kajiyama, Xianfen Wang, Hiroki Inuma, Ryohei Morita, Kazuma Gotoh, Atsuo Yamada

[Flexible MXene Nanosheets: Negative Electrode Materials for Lithium-Ion and Sodium-Ion Batteries](#)

---

## Symposium 3: Batteries for Tomorrow's World

---

**Room : 201C**

*Chaired by:* Xuejie Huang

14:00 to 14:20 Invited

**Yi Cui** (Department of Materials Science and Engineering, Stanford University, Stanford, USA)

[Materials Design for Lithium-Sulfur Batteries](#)

14:20 to 14:40

**Dauren Batyrbekuly** (Institute of Batteries, Institute of Batteries, Astana, Kazakhstan), Almagul Mentbayeva, Yongguang Zhang, Indira Kurmanbayeva, Kuralay Korzhynbayeva

[Reinforced composite gel-polymer electrolytes for lithium-sulfur batteries](#)

14:40 to 15:00

**Xiaogang Zhang** (College of Material Science and Engineering, Nanjing University of Aeronautics and Astronautics, Nanjing, China), Guiyin Xu, Bing Ding, Hui Dou, Ping Nie, Jin Pan

[Insights into the Absorption Mechanism of Carbon Nanotube Paper-Titanium Dioxide as a Multifunctional Barrier for Lithium-Sulfur Batteries](#)

15:00 to 15:20

**Almagul Mentbayeva** (Institute of Batteries, Institute of Batteries, Nazarbayev University, Astana, Kazakhstan), Aishuak Konarov, Ayaulym Belgibayeva, Toru Hara, Nurzhan Umirov, Zagipa Bakenova

[Free standing sulfur-composite cathode for lithium-sulfur batteries](#)

15:20 to 15:40

**Heng-Liang Wu** (Department of Chemistry, University of Illinois Urbana-Champaign, Urbana, USA), Laura A. Huff, Andrew Gewirth

[In-situ Raman Spectroscopy and EQCM study of Lithium-Sulfur Batteries](#)

15:40 to 16:00

**Jason Fang** (Material and Chemical Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan)

[A High Energy, Long-life Li-S Battery Enabled by Mille-Feuille Structure Electrode](#)

16:00 to 16:20

**Matthew Lacey** (Department of Chemistry - Ångström Laboratory, Uppsala University, Uppsala, Sweden), Anurag Yalamanchili, Viking Oesterlund, Fabian Jeschull, Julia Maibach, Carl Tengstedt, Kristina Edström, Daniel Brandell

[Self-Discharge and Cycling Stability in the Li-S System: Where Every Cell Component Plays a Role](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Yong Yang** (Chemistry, Xiamen University, Xiamen, China), Sihui Wang, Xuehang Wu, Shouding Li, Jianghuai Guo, Yixiao Li

[Enhancing electrochemical performance of layered oxide cathode materials for Li/Na ion batteries](#)

17:00 to 17:20

**Yuebin Yang** (Department of Chemical and Biomolecular Engineering, The Hong Kong University of Science and Technology, Hong Kong, China), Hui Xu

[Carbonized Polydopamine/Sulfur Composite with One-Dimensional Structure for High Performance Lithium Sulfur Batteries](#)

17:20 to 17:40

**Elie Paillard** (Helmholtz Institute Muenster, Forschungszentrum Juelich, Muenster, Germany), Lorenzo Grande, Marija Kirchhöfer, Irene Osada, Stephan Koch, Stefano Passerini

[Ionic Liquids and Polymer Electrolytes for Li-metal Batteries](#)

17:40 to 18:00

**Nadège Bonnet-Mercier** (Byon Initiative Research Unit (IRU), RIKEN, Wakoshi, Japan), Raymond Wong, Hye Ryung Byon

[Understanding Na-O<sub>2</sub> Electrochemistry in Non-aqueous Na-O<sub>2</sub> Batteries](#)

18:00 to 18:20

**Satoshi Fujiki** (AR-3, Samsung R&D Institute Japan, 2-1-11, Semba Nishi, Minoh City, Japan)

[Development of a high energy density sulfide-based all-solid-state battery](#)

---

## Symposium 5: Novel Insights to Electrochemical Capacitors

---

**Room : 101A**

*Chaired by:* Masayuki Morita, Soo-Gil Park, Patrice Simon and Wataru Sugimoto

14:00 to 14:20

**Etsuro Iwama** (Applied Chemistry, Tokyo University of Agriculture and Technology, Tokyo, Japan), Takumi Furuhashi, Yuta Abe, Keita Okazaki, Shintaro Aoyagi, Junichi Miyamoto, Wako Naoi, Katsuhiko Naoi

[Ultrafast Electrochemical Characteristics of nc-TiO<sub>2</sub> \(B\)/Nanocarbon Composites for Hybrid Capacitor System](#)

14:20 to 14:40

**Wan-Yu Tsai** (CIRIMAT, Université Paul Sabatier, Toulouse, France), John M. Griffin, Alexander C. Forse, Clare P. Grey, Pierre-Louis Taberna, Patrice Simon

[In-situ Electrochemical Quartz Crystal Microbalance \(EQCM\) Study of Ion Dynamics and Charge Storage Mechanism for Supercapacitors](#)

14:40 to 15:00

**Tu-Ting Weng** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), H.A. Pan, R. C. Lee, T.Y. Huang, Y. Chu, J.F. Lee, H.S. Sheu, Nae-Lih Wu

[Spatially Confined MnO<sub>2</sub> Nanostructure Enabling Long-Term Reversible Two-Electron Transfer in Mixed Pseudocapacitor-Battery Electrode](#)

15:00 to 15:20

**Chung-Ting Tsai** (Research and Development, China Steel Chemical Corporation, Kaohsiung, Taiwan), Jing-Mei Li, Chi-Shyan Mai, Sen-Tsan Shen, Ming-Da Fang

[The influence of Pore Size Distribution and surface area both are analyzed by QSDFT on capacitance and ESR of EDLC consists of activated carbon from coal tar pitch](#)

15:20 to 15:40

**Krzysztof Fic** (Institute of Chemistry and Technical Electrochemistry, Poznan University of Technology, Poznan, Poland), Jakub Menzel, Elzbieta Frackowiak

[Faradaic and Non-faradaic Interactions at the Electrode/Electrolyte Interface in Electrochemical Capacitors](#)

15:40 to 16:00

**Laura Coustan** (ICGM-AIME, Institut Charles Gerhardt, UMR 5253 CNRS, Université Montpellier, Montpellier, France), Vanessa Armel, Frederic Jaouen, Frédéric Favier

[Metal Organic Frameworks as precursors of porous carbon materials for supercapacitor applications](#)

16:00 to 16:20

**Pawel Jezowski** (Institute of Chemistry and Technical Electrochemistry, Poznan University of Technology, Poznan, Poland), Olivier Crosnier, Thierry Brousse, François Béguin

[New materials for in-situ pre-lithiation of the graphite anode in lithium ion capacitor](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Yongyao Xia** (Chemistry, Fudan University, Shanghai, China), Yanfang Song, Dandan Zhou

[Nitrogen-doped Mesoporous Carbon for Supercapacitor Application](#)

17:00 to 17:20 Invited

**Frédéric Favier** (Institut Charles Gerhardt Montpellier, UMR 5253 CNRS Université de Montpellier, Montpellier, France), Peng-Cheng Gao, Laura Coustan, Wan-Yu Tsai, Carlos Pérez, Patricia Russo, Yury Gogotsi, Nicola Pinna, Patrice Simon

[Graphene-based Electrochemical Capacitors](#)

17:20 to 17:40 Invited

**Soo-Gil Park** (Industrial Engineering Chemistry, Chungbuk National University, Cheongju, Korea), Joeng-Jin Yang, Han-Joo Kim, Young-Jae Yuk

[Electrochemical Characteristics of Composite Materials as Carbon & Metal Oxide for Hybrid Capacitor](#)

17:40 to 18:00 Invited

**Soshi Shiraishi** (Gunma University, Graduate School of Science and Technology, Kiryu, Japan), Yasuyoshi Shiraishi, Hiroyuki Fujimoto

[Graphite-Fluoride Lithium Hybrid Capacitor](#)

18:00 to 18:20 Invited

**Jong-Huy Kim** (Energy Storage Research Lab., Korea Institute of Energy Research, Daejeon, Korea), Young-Joon Oh, Jung-Joon Yoo, Yong-Il Kim, Jae-Kook Yoon

[Oxygen Functional Groups of Incompletely Reduced Graphene Oxides for a Thin-film Electrode of Supercapacitor](#)

18:20 to 18:40

**JunHui Jeong** (Material Science and Engineering, Yonsei Univ., Seoul, Korea), Hyun-Kyung Kim, Suk-Woo Lee

[Fabrication of Graphene Microspheres for High Performance Supercapacitor Applications](#)

## Symposium 8: Corrosion and Passivity

Room : 201D

Chaired by: Dirk Engelberg and Shinji Fujimoto

14:00 to 14:20

**Oliver Chyan** (Department of Chemistry, University of North Texas, Denton, USA)

[Micro-pattern Corrosion Screening on Bimetallic Corrosion for Microelectronic Application](#)

14:20 to 14:40

**Jun-Seob Lee** (Graduate School of Chemical Sciences and Engineering, Hokkaido University, Sapporo, Japan), Yuichi Kitagawa, Takayuki Nakanishi, Yasuchika Hasegawa, Koji Fushimi

[Passivation Behavior of Type-316L Stainless Steel in the Presence of Hydrogen Sulfide Ions Generated from Liquid-Phase Ion Gun](#)

14:40 to 15:00

**Peter Keech** (Nuclear Waste Management Organization, Toronto, Canada), Sridhar Ramamurthy, Rachel Partovi-Nia, Jian Chen, Rebecca Jacklin, David Shoesmith

[Copper Coatings for Used Nuclear Fuel Containers: Corrosion Testing](#)

15:00 to 15:20

**Xavier Feaugas** (La Rochelle University, LaSIE UMR 7356 CNRS, La Rochelle University, La Rochelle, France), Niusha Shakibi Nia, Matthieu Lagarde, Juan Creus, Catherine Savall

[Electrochemical behavior of electrodeposited Ni-W nanostructured alloys](#)

15:20 to 15:40

**Delphine Veys-Renaux** (Institut Jean Lamour, Université de Lorraine, CNRS, Vandoeuvre les Nancy, France), Emmanuel Rocca, Nouha M'hiri, Solenn Reguer, Irina Ioannou, Mohammed Ghoul

[Corrosion inhibition of steel by flavonoid model molecules: naringin, neohesperidin, rutin](#)

15:40 to 16:20 Keynote

**Hans-Henning Strehblow** (Institute of Physical Chemistry, Heinrich-Heine-Universitaet-Duesseldorf, Duesseldorf, Germany)

[The Investigation of Passivity of Metals Studied by Surface Analytical Methods, a Review](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Nadine Pebere** (CIRIMAT, CNRS, Toulouse, France), Fatah Chiter, Corinne Lacaze-Dufaure, Sabrina Marcelin, Hao Tang

[Corrosion Inhibition of Pure Aluminium by 8-Hydroxyquinoline: Combined Electrochemical and DFT Studies](#)

17:00 to 17:20

**I-Wen Huang** (Materials Science and Engineering, The Ohio State University, Columbus, USA), Rudolph Buchheit

[Assessing Uniform Corrosion of Aluminum Alloys 2024-T3, 6061-T6, and 7075-T6 in Aqueous Immersion Conditions](#)

17:20 to 17:40

**Hiroaki Tsuchiya** (Division of Materials and Manufacturing Science, Osaka University, 2-1 Yamada-oka, Suita, Japan), Min-Su Kim, Toshiaki Erami, Yuki Otani, Shinji Fujimoto

[Alloy Anodization in Fluoride-Containing Electrolytes](#)

17:40 to 18:00 Invited

**Koji Fushimi** (Faculty of Engineering, Hokkaido University, Sapporo, Japan), Haruya Ikeyama, Yuichi Kitagawa, Takayuki Nakanishi, Yasuchika Hasegawa, Mikito Ueda, Toshiaki Ohtsuka

[Photo-electrochemical Degradation of Anodized Titanium Surface Observed using EIS and Ellipso-microscopy](#)

18:00 to 18:20

**Khurram Shahzad** (Graduate School of Chemical Sciences and Engineering, Hokkaido University, Sapporo, Japan)

[Influence of water concentration on growth efficiency of barrier-type anodic film on magnesium](#)

18:20 to 18:40

**Pei-Yu Lai** (Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Jinn P. Chu, Bing-Joe Hwang

[Metallic Glass Coatings for Aluminum Current Collectors – Corrosion Inhibition](#)

---

## Symposium 9: Electrocatalytic Materials

---

Room : 201EF

*Chaired by:* Kensaku Kodama, Dangsheng Su, Sandra Temmel and Jong-Sung Yu

14:00 to 14:20 Invited

**Dangsheng Su** (Shenyang National Laboratory for Materials Science, Institute of Metal Research, Chinese Academy of Science, Shenyang, China)

[Investigation of the Structure of Fe–N–C Complexes for Oxygen Reduction Reactions](#)

14:20 to 14:40

**Kamiya Kazuhide** (Department of Applied Chemistry, The University of Tokyo, Tokyo, Japan), Ryo Kamai, Kazuhito Hashimoto, Shuji Nakanishi

[Platinum-modified Covalent Triazine Frameworks as Methanol-tolerant Oxygen Reduction Electrocatalysts](#)

14:40 to 15:00

**Deli Wang** (School of Chemistry and Chemical Engineering, Huazhong University of Science and Technology, Wuhan, China), Jing Zhu, Sufen Liu, Jie Wang, Zexing Wu

[Novel Structured Pt-Based Intermetallic Electrocatalysts for ORR](#)

15:00 to 15:20

**Bart Geboes** (Research Group Advanced Reactor Technology (ART), University of Antwerp, Antwerp, Belgium), Jon Ustarroz, Kadir Sentosun, Sara Bals, Annick Hubin, Tom Breugelmans

[Activity and Stability of Electrodeposited Nanoporous Catalysts towards the Oxygen Reduction Reaction](#)

15:20 to 15:40

**Ifan Stephens** (Physics, Technical University of Denmark, Kongens Lyngby, Denmark), Maria Escudero-Escribano, Ulrik Grønbjerg, Vladimir Tripkovic, Jakob Schiøtz, Jan Rossmeisl, Ib Chorkendorff

[Tuning the activity and stability of Pt for oxygen reduction by means of the lanthanide contraction](#)

15:40 to 16:00

**Silver Sepp** (Institute of Chemistry, University of Tartu, Tartu, Estonia), Jaak Nerut, Kersti Vaarmets, Indrek Tallo, Enn Lust

[Performance of PEMFC Half Cells Prepared Using Hierarchical Microporous-Macroporous Carbon Supported Pt-Catalyst](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Sandra Temmel** (General Energy Department, ETH Zürich/ Paul-Scherrer-Institute, Villigen, Switzerland), Emiliana Fabbri, Daniele Pergolesi, Thomas Lippert, Thomas Justus Schmidt

[Investigation of ORR activity of strained thin film Pt electrocatalyst produced by pulsed laser deposition](#)

17:00 to 17:20

**Kensaku Kodama** (Fuel Cell System Laboratory, Toyota Central R&D Labs. Inc., Nagakute, Japan), Ryosuke Jinnouchi, Naoko Takahashi, Hajime Murata, Yu Morimoto

[ORR activities of Au-Modified Stepped Pt Single Crystal Electrodes](#)

17:20 to 17:40

**Qingli Hao** (School of Chemical Engineering, Nanjing University of Science and Technology, Nanjing, China),  
Wu Lei, Lei Lu, Xifeng Xia

[Synthesis of CoFe<sub>2</sub>O<sub>4</sub>/ Nitrogen-doped Graphene and its Catalytic Performance for ORR](#)

17:40 to 18:00

**Gert Göransson** (Department of Chemistry and Molecular Biology, University of Gothenburg, Gothenburg, Sweden), Elisabet Ahlberg, Alexander Björling

[A study of the Formation of Co<sub>1-x</sub>Fe<sub>x</sub>S<sub>2</sub> in Microwave Synthesis and its Electrocatalytic Properties towards Oxygen Reduction and Hydrogen Evolution](#)

18:00 to 18:20

**Adriano Gomes** (Department of Chemistry and Molecular Biology, University of Gothenburg, Gothenburg, Sweden), Zareen Abbas, Nina Simic, Mats Wildlock, Elisabet Ahlberg

[Electrochemical Water Reduction in Highly Concentrated Electrolytes: Theory and Experiments](#)

18:20 to 18:40

**Pawel J. Kulesza** (Department of Chemistry, University of Warsaw, Warsaw, Poland)

[Development and Characterization of Nanostructured Multifunctional Materials for Photoelectrochemical and Electrocatalytic Reduction of Carbon Dioxide and Water Splitting](#)

---

## Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy

---

**Room : 101B**

*Chaired by:* Ignacio González and Ricardo Salazar

14:00 to 14:20 Invited

**Javier Llanos** (Department of Chemical Engineering, University of Castilla-la Mancha, Ciudad Real, Spain), Sabri Kalkan, Alexandra Raschitor, Bahadır K. Körbahti, Pablo Cañizares, Manuel Andres Rodrigo

[Development of Reactive Ion Exchange Membranes for Electro-Disinfection](#)

14:20 to 14:40

**Henry Bergmann** (FB 6 & 7, Anhalt University, Köthen/Anh., Germany), Wido Schmidt, Jens Hartmann

[On the necessity of field studies for direct electrochemical drinking water disinfection](#)

14:40 to 15:00 Invited

**Onofrio Scialdone** (Dipartimento di ingegneria chimica, gestionale, informatica, Università degli Studi di Palermo, Palermo, Italy), Adriana D'Angelo, Alessandro Galia, Simona Sabatino, Fabrizio Vicari

[Abatement of pollutants in water by different electrochemical approaches](#)

15:00 to 15:20

**Emmanuel Mousset** (Civil and Environmental Engineering, National University of Singapore (NUS), Singapore, Singapore), Zuxin Wang, Olivier Lefebvre

[Towards a More Competitive Advanced Electrochemical Technology: New Carbon-Based Electrodes Combination for Wastewater Treatment](#)

15:20 to 15:40

**Tsuyoshi Ochiai** (Photocatalyst Group, Kanagawa Academy of Science and Technology, Kawasaki, Japan), Mio Hayashi, Shoko Tago, Kazuo Hirota, Takeshi Kondo, Kazuhito Satomura, Akira Fujishima

[Flexible Pinpoint Electrolysis Unit by Using of Boron-doped Diamond Powder \(BDDP\) Based Polymer Composites for Dental Treatments](#)

15:40 to 16:00 Invited

**Philippe Vernoux** (IRCELYON, CNRS, Villeurbanne, France)

[Electrochemical activation of environmental catalysis](#)

16:00 to 16:20

**Carlos Alberto Martinez-Huitle** (Institute of Chemistry, Federal University of Rio Grande do Norte, NATAL, Brazil), Ana S. dos Santos Fajardo, Maiara Barbosa Ferreira, Rui C. Martins, Djalma Ribeiro da Silva, Rosa M. Quinta-Ferreira

[Electrochemical Sequential Flow Reactors for removing Textile Dyes Using Different Anodes](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Takayuki Homma** (Applied Chemistry, Waseda University, Tokyo, Japan), Yingying Sun, Masahiro Kunimoto, Mikiko Saito, Masahiro Yanagisawa

[In situ Analysis of Electrochemical Fabrication Processes Using Raman Spectroscopy with Plasmonic Sensors](#)

17:00 to 17:20

**Priscilla Baker** (Chemistry, University of the Western Cape, Bellville, South Africa), Meryck Ward, Euodia Hess, Stephen Mailu, Christopher Sunday, Milua Masikini, Emmanuel Iwuoha

[Electrochemical protocols for measurement of polycyclic aromatic hydrocarbons in environmental samples](#)

17:20 to 17:40

**Nick Daems** (Centre for Surface Chemistry and Catalysis, K.U. Leuven, Heverlee, Belgium), Jonatan Wouters, Ivo Vankelecom, Paolo Pescarmona

[Non-noble metal-containing doped graphitic carbons as electrocatalysts for the cogeneration of electricity and aniline.](#)

17:40 to 18:00

**Geir Martin Haarberg** (Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway), Junli Xu

[Sustainable Electrolysis for Electrowinning and Electrorefining of Metals in Molten Salts and Aqueous Electrolytes](#)

18:00 to 18:20

**Tom Breugelmans** (Research group Advanced Reactor Technology (ART), University of Antwerp, Hoboken, Belgium), Bart Vanrenterghem, Bart Geboes, Jon Ustarroz, Sara Bals, Annick Hubin

[Influence of the morphology of electrodeposited nanoparticles on their activity for the cyclisation reaction of allyl 2-bromobenzyl](#)

18:20 to 18:40

**Carmen Maria Fernandez Marchante** (Chemical Engineering, University of Castilla La Mancha, Ciudad Real, Spain), Yeray Asensio, Eduardo Penteado, Iciar Begoña Montes, Marcelo Zaiat, Justo Lobato, Pablo Cañizares, Ernesto Gonzalez, Manuel Andres Rodrigo

[Influence of electrode material on microbial fuel cell treating a synthetic and a winery wastewater](#)

## Symposium 12: Physical Electrochemistry: Spectroscopic, Structural, and Theoretical Investigations of the Electrified Interface

**Room : 101C**

*Chaired by:* Federico Calle-Vallejo, Axel Gross, Katharina Krischer, Jan Rossmeisl

14:00 to 14:40 Keynote Invited

**Jan Rossmeisl** (Department of Chemistry, University of Copenhagen, København, Denmark)

[Special Sites in Electrocatalysis](#)

14:40 to 15:00

**Katharina Krischer** (Physik-Department, Technische Universität München, Garching bei München, Germany), Philipp Bauer, Munir Salman, Antoine Bonnefont

[Peculiar Excitation Waves during CO Electrooxidation on Pt Electrodes in an Electrochemical Flow Cell](#)

15:00 to 15:20 Invited

**Aliaksandr Bandarenka** (Department of Physics, Technische Universität München, Garching, Germany)

[Oxygen Electroreduction at Non-uniform Pt Surfaces: From Model Electrodes to Nanostructured Catalysts](#)

15:20 to 15:40 Invited

**Federico Calle-Vallejo** (Laboratoire de Chimie, ENS Lyon, Lyon, France), Jakub Timoczko, Viktor Colic, Quang Huy Vu, Marcus D. Pohl, Karina Morgenstern, David Loffreda, Philippe Sautet, Wolfgang Schuhmann, Aliaksandr Bandarenka

[Designing Better Electrocatalysts by Simply Counting Surface nearest Neighbors](#)

15:40 to 16:00

**Ali Malek** (Department of Chemistry, Simon Fraser University, Burnaby, Canada), Mohammad J. Eslamibidgoli, Michael Eikerling

[DFT Study of Surface Charging Effects on Oxygen Covered Pt\(111\)](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Sara Panahian Jand** (Institut für Chemie und Biochemie, Freie Universität Berlin, Berlin, Germany), Payam Kaghazchi

[Theoretical Simulation of Solid Electrolyte Interphases](#)

17:00 to 17:20

**Qingli Zou** (Mechanical and Automation Engineering, The Chinese University of Hong Kong, Shatin, Hong Kong, China), Yi-Chun Lu

[Influence of Electrolyte on Sulfur Redox Reactions: Combined RRDE and in situ UV-VIS Studies](#)

17:20 to 17:40

**Shen Ye** (Catalysis Research Center, Hokkaido University, Sapporo, Japan), Yu Qiao

[In-situ Study of Oxygen Reduction in DMSO Solution](#)

17:40 to 18:00

**Ove Oll** (Institute of Chemistry, University of Tartu, Tartu, Estonia), Tavo Romann, Enn Lust

[An Infrared Study of the Few-Layer Graphene | Ionic Liquid Interface: Correlation between Electronic and Ionic Surface Structure](#)

18:00 to 18:20

**Matej Velicky** (School of Chemistry, University of Manchester, Manchester, United Kingdom), Peter S. Toth, Mark A. Bissett, Ian A. Kinloch, Konstantin S. Novoselov, Robert A.W. Dryfe

[Electrochemistry of Two-Dimensional Materials](#)

18:20 to 18:40

**Katsuyoshi Ikeda** (Graduate School of Engineering, Nagoya Institute of Technology, Nagoya, Japan)

[Surface enhanced Raman observation of molecular adsorbates on atomic local surface sites](#)

## Symposium 15: Electrochemical Engineering from a Quantum Description to the Plant Modeling: Experiments and Design across Length Scale

**Room : 102**

*Chaired by:* Jaeyoung Lee

14:00 to 14:40 Keynote Invited

**Bongjin Simon Mun** (Gwangju Institute of Science and Technology, Gwangju, Korea)

[Development of Ambient Pressure XPS and its Applications to Electrochemistry](#)

14:40 to 15:00

**Byungchan Han** (Chemical and Biomolecular Engineering, Yonsei university, Seoul, Korea), Seunghyo Noh

[Multi-scale Computational Design of Multi-functional Catalyst Materials for Fuel Cells Beyond Conventional Bulk Pt](#)

15:00 to 15:20

**Guadalupe Ramos-Sanchez** (Departamento de Química, Universidad Autónoma Metropolitana, Mexico City, Mexico)

[A multi-scale model to account for the electrochemical response of the oxygen reduction reaction on highly active graphene nanosheets in alkaline conditions](#)

15:20 to 15:40 Invited

**Trung Van Nguyen** (Chemical and Petroleum Engineering, University of Kansas, Lawrence, USA)

[Water Management in Proton Exchange Membrane Fuel Cells by Materials Design and Engineering](#)

15:40 to 16:20 Keynote

**Tetsuya Mashio** (Research Division, Nissan Motor Co., Ltd., Yokosuka, Japan), Atsushi Ohma, Takashi Tokumasu

[Analysis of PEMFC Catalyst Layers from Fabrication Process to Performance](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Daniel Brandell** (Department of Chemistry, Uppsala University, Uppsala, Sweden), Shruti Srivastav, Matthew Lacey

[Combined Finite Element Modelling and EIS Studies for SoC Indication in Rechargeable Li-Ion Batteries](#)

17:00 to 17:20 Invited

**Christine Frayret** (UFR des Sciences, LRCS-CNRS UMR 7314, Université de Picardie Jules Verne, Amiens, France), Daniele Tomerini, Carlo Gatti, Yann Danten

[Catalyzing Innovation in Organic Battery Electrodes from Computational Modelling](#)

17:20 to 17:40 Invited

**Payam Kaghazchi** (Physikalische und Theoretische Chemie, Freie Universität Berlin, Berlin, Germany)

[Theoretical Study of Lithium-Sulfur Battery Cathodes](#)

17:40 to 18:00

**Yinghui Yin** (Laboratoire de Réactivité et Chimie des Solides (LRCS), Université de Picardie Jules Verne & CNRS, Amiens, France), Guillaume Blanquer, Matias A. Quiroga, Alejandro A. Franco

[Boosting Lithium Air Batteries from a Multiscale Modeling Approach](#)

18:00 to 18:20

**Seunghwa Lee** (School of Environmental Science and Engineering, Gwangju Institute of Science and Technology, Gwangju, Korea), Hansaem Jang, Jaeyoung Lee

[The pH Effect on the Electrochemical Reduction of Carbonate Species over Metal Oxide Electrodes](#)

18:20 to 18:40

**Hyungjun Kim** (Graduate School of EEWS, Korea Advanced Institute of Science and Technology, Daejeon, Korea), Hyung-Kyu Lim, Hyeyoung Shin

[Toward efficient electrochemical conversion of CO<sub>2</sub>: catalyst design accelerated by simulation-based screening](#)

Wednesday, 7 October 2015

ROOMS:	101A	101B	101C	101D	102	103	201AB	201EF	201C	201D

11:50 - 12:10										
12:10 - 12:30										

# Wednesday, 7 October 2015 - Morning

---

## Plenary Lecture

Room : Plenary Hall

*Chaired by:* Zhong-Qun Tian

08:15 to 09:15

**Li-Jun Wan** (Institute of Chemistry, Chinese Academy of Sciences, Beijing, China)

[Nanomaterials for Energy Conversion and Storage: Structure Design and In-Situ Monitoring](#)

---

## Symposium 1: New Directions in Analytical Electrochemistry

Room : 103

*Chaired by:* Osamu Niwa and Patrick Unwin

09:30 to 10:10 Keynote

**J. Justin Gooding** (School of Chemistry, The University of New South Wales, Sydney, Australia), Moinul Choudhury, Simone Ciampi, Stephen G. Parker, Ying Yang, Roya Tavallaie, Leila Zarei, Vinicius Goncales

[Light Activated Electrochemistry: A strategy for performing voltammetry on a monolithic surface where you want, when you want with micron scale spatial resolution](#)

10:10 to 10:30

**Emmanuel Iwuoha** (Department of Chemistry, SensorLab, University of Western Cape, Cape Town, South Africa)

[Biocompatible Quantum Dots and Conducting Polymer Nanocomposites in Disease Signalling Biosensors](#)

10:30 to 10:50 Invited

**Sabine Szunerits** (IEMN, University Lille, Villeneuve d'Ascq, France)

[Reduced graphene oxide modified electrodes: from glucose sensing to electrochemical delivery of insulin](#)

10:50 to 11:10

Coffee Break

## Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications

**Room : 101D**

*Chaired by:* Alexandra Bondarenko and Shen-Ming Chen

09:30 to 09:50

**Yasufumi Takahashi** (WPI-AIMR, Tohoku University, Sendai, Japan), Sen Mustafa, Hiroki Ida, Hitoshi Shiku, Tomokazu Matsue

[Improving the Electrochemical Measurement Sensitivity of SECM-SICM by using Pt Electrodeposited Carbon Nanoelectrode](#)

09:50 to 10:10

**Ming-Chang Yang** (Department of Chemical Engineering, National Cheng Kung University, Tainan, Taiwan), Yi-Kai Chih, Ya-Yun Zhan

[Nitrogen-doped Carbon Electrodes for Simultaneous Detection of Dopamine, Uric Acid and Ascorbic Acid](#)

10:10 to 10:50 Keynote

**Woonsup Shin** (Department of Chemistry, Sogang University, Seoul, Korea)

[Development of Drug Delivery Devices Based on Nongassing Electroosmotic Pump](#)

10:50 to 11:10

Coffee Break

## Symposium 3: Batteries for Tomorrow's World

**Room : 201AB**

*Chaired by:* Yong Yang

09:30 to 10:10 Keynote

**Claude Delmas** (ICMCB, CNRS, Pessac, France)

[An Overview of the Behavior of Overlithiated  \$\text{Li}\(\text{Li}, \text{Mn}, \text{Co}, \text{Ni}\)\text{O}\_2\$  Layered Oxides In Lithium-ion Batteries](#)

10:10 to 10:30

**Shou-Yu Shen** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China)

[Superior electrochemical performance of Li-rich  \$\text{Li}\_{1.188}\text{Ni}\_{0.198}\text{Co}\_{0.087}\text{Mn}\_{0.553}\text{O}\_2\$  cathode material by coating Li-La-Zr-O solid electrolyte](#)

10:30 to 10:50

**Shinya Suzuki** (Department of Applied Chemistry, School of Engineering, The University of Tokyo, Tokyo, Japan), Masaru Miyayama

[Electrode properties of the restacked  \$\text{MnO}\_2\$ -based nanosheets with vacancy defects](#)

10:50 to 11:10

Coffee Break

## Symposium 3: Batteries for Tomorrow's World

Room : 201C

Chaired by: K. Zaghib

09:30 to 09:50

**Fridolin Röder** (Institute of Energy and Process Systems Engineering, Technical University of Braunschweig, Braunschweig, Germany), Ulrike Krewer

[Fundamental Analysis of Lithium-ion Battery Performance and Degradation in Context of Particle Size Distribution](#)

09:50 to 10:10

**Fabian Jeschull** (Department of Chemistry, Ångström Laboratory, Uppsala University, Uppsala, Sweden), Matthew Lacey, Daniel Brandell

[Functional Binders - SEI Formers, Dispersants and Local Electrolyte Components](#)

10:10 to 10:30

**Po-Han Lee** (Department of Materials Engineering, Tatung University, Taipei City, Taiwan), She-huang Wu

[Unexpected Cycle Aging of a Commercial 18650 Cell](#)

10:30 to 10:50

**Nan Lin** (Institute of Energy and Process Systems Engineering, TU Braunschweig, Braunschweig, Germany), Ulrike Krewer

[Novel Electrochemical-Thermal Modeling for Lithium-ion Battery Design based on a Fast Reduced P2D Electrochemical Model](#)

10:50 to 11:10

Coffee Break

WEDNESDAY AM

## Symposium 4: Advances in Fuel Cells from Materials to Systems

Room : 102

Chaired by: Hiroyuki Uchida

09:30 to 09:50 Invited

**Eiichi Yasumoto** (Corporate Engineering Division, Appliances Company, Panasonic Corporation, 3-1-1 Yagumo-naka-machi, Moriguchi City, Japan), Masataka Ozeki

[Evolution of "ENE-FARM" and the Activities for the Market Expansion in Panasonic](#)

09:50 to 10:10 Invited

**Tae-Hyun Yang** (Fuel Cell Research Center, Korea Institute of Energy Research, Daejeon, Korea), Young-Jun Sohn, Minjin Kim, Seung-Gon Kim

[Design and Development of a Fuel Cell Power Module for High Altitude and Long Endurance Unmanned Aerial Vehicles](#)

10:10 to 10:30

**Michael Fleige** (Department of Chemistry and Nano-Science Center, University of Copenhagen, Copenhagen, Denmark), Gustav Wiberg, Matthias Arenz

[RDE system for ORR measurements at elevated \(>100 °C\) temperature and pressure conditions](#)

10:30 to 10:50

**Hiroki Habazaki** (Faculty of Engineering, Hokkaido University, Sapporo, Japan)

[Oxygen Reduction Activity and Durability of Pt Electrocatalysts Supported on Platelet Carbon Nanofibers](#)

10:50 to 11:10

Coffee Break

## Symposium 5: Novel Insights to Electrochemical Capacitors

**Room : 101A**

*Chaired by:* Elzbieta Frackowiak

09:30 to 10:10 Keynote

**Thierry Brousse** (Institut des Matériaux Jean Rouxel (IMN), Université de Nantes, Nantes, France), Mylène Brachet, Jean Le Bideau, Dorian Gaboriau, Gérard Bidan, Pascal Gentile, Said Sadki

[Ionogels as safe and thermally stable electrolytes for macro and micro electrochemical capacitors](#)

10:10 to 10:30

**Andrea Balducci** (Helmholtz Institute Ulm, Helmholtz Institute Ulm - Karlsruhe Institute of Technology, Ulm, Germany), Christoph Schütter, Sebastian Pohlmann, Claudia Ramirez-Castro, Tamara Husch, Martin Korth

[Innovative conducting salts and solvents for advanced electrochemical double layer capacitors](#)

10:30 to 10:50

**Sonia Dsoke** (ECM, ZSW, Ulm, Germany), Tong Zhang, Bettina Fuchs, Marco Secchiaroli, Serife Kaymaksiz, Margret Wohlfahrt-Mehrens

[Combination of Li-salt-based electrolytes with activated carbon electrodes for the development of hybrid battery-supercapacitors](#)

10:50 to 11:10

Coffee Break

WEDNESDAY AM

## Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication

**Room : 101C**

*Chaired by:* Dow Wei-Ping and Shu-Hua Cheng

09:30 to 10:10 Keynote

**Chih Chen** (Materials Science and Engineering, National Chiao Tung Univ, Hsin-chu, Taiwan)

[Electrodeposition of Highly \(111\)-oriented Nanotwinned Cu and its Application](#)

10:10 to 10:30 Invited

**Rohan Akolkar** (Chemical and Biomolecular Engineering, Case Western Reserve University, Cleveland, USA), Chang-Jung Hsueh, Dai Shen, Mirko Antloga, Craig Virnelson, Uziel Landau, Mark DeGuire

[A Novel Titanium Electrowinning Process Using Specialized Segmented Diaphragms](#)

10:30 to 10:50

**Atsushi Kitada** (Department of Materials Science and Engineering, Kyoto University, Kyoto, Japan), Yuu Kang, Kai Nakamura, Kazuhiro Fukami, Kuniaki Murase

[Room Temperature Electrodeposition of Elemental Magnesium and Aluminum from Glyme-Based Electrolytes](#)

10:50 to 11:10

Coffee Break

---

## Symposium 8: Corrosion and Passivity

---

**Room : 201D**

*Chaired by:* Mark E. Orazem

09:30 to 10:10 Keynote

**Bernard Tribollet** (UMR8235 LISE, UPMC - CNRS, Paris, France), Sara Chakri, Isabelle Frateur, Frederic Kanoufi, Eliane Sutter, Vincent Vivier

[Analysis by EIS of Cathodic Reactions on Carbon Steel in Aerated Solution at pH 13](#)

10:10 to 10:30

**Yu-Min Chen** (Department of Chemical Engineering, University of Florida, Gainesville, USA), Mark E. Orazem

[Analysis of Corrosion Behavior of ASTM A416 Steel by Electrochemical Impedance Spectroscopy](#)

10:30 to 10:50

**Sara Munktel** (Department of Chemistry - Ångström Laboratory, Uppsala Universitet, Uppsala, Sweden), Leif Nyholm, Fredrik Björefors

[Towards high-throughput Corrosion Screening using Bipolar Electrochemistry](#)

10:50 to 11:10

Coffee Break

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 201EF**

*Chaired by:* Shawn D. Lin

09:30 to 10:10 Keynote

**Lin Zhuang** (Department of Chemistry, Wuhan University, Wuhan, China)

[Alkaline polymer electrolyte fuel cells: materials and catalysis](#)

10:10 to 10:30 Invited

**Wei Xing** (State Key Laboratory of Electroanalytical Chemistry, Changchun Institute of Applied Chemistry, Jilin, China), Jianbing Zhu, Junjie Ge, Changpeng Liu, Meiling Xiao

[Exploration of efficient low-platinum and non-platinum catalysts for oxygen reduction reaction](#)

10:30 to 10:50

**Atif Koca** (Chemical Engineering Department, Marmara University, Istanbul, Turkey), Mehmet Aydemir, Duygu Akyüz, Burag Agopcan, Cevat Sarioğlu, M. Kasim Sener, Fatma K. Albayrak

[Electrocatalytic and Photocatalytic Hydrogen Production](#)

10:50 to 11:10

Coffee Break

---

## Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy

---

**Room : 101B**

*Chaired by:* Carlos Alberto Martinez-Huitle and Henry Bergmann

09:30 to 09:50 Invited

**Carlos Ponce de Leon** (Faculty of Engineering and the Environment, University of Southampton, Southampton, United Kingdom), Rachel D. McKerracher, Horacio A. Figueredo-Rodriguez, Frank C Walsh

[A Bifunctional Air Electrode Catalyzed by Transition Metal Ferricyanide Derivatives for an Iron-air battery](#)

09:50 to 10:10

**Mitsuru Wakisaka** (Fuel Cell Nanomaterials Center, University of Yamanashi, Kofu, Japan), Masashi Kunitake

[Direct Electrochemical Hydrogenation of Aromatic Molecules at Pt Electrode in Microemulsion Electrolyte Solution](#)

10:10 to 10:30

**Min-Hsin Yeh** (School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, USA), Long Lin, Zhong Lin Wang

[Motion-driven Electrochromic Reactions for Self-powered Smart Window System](#)

10:30 to 10:50

**Laura Valero** (Research Electronics Departament, Universidad Autónoma Del Estado de México, Toluca, Mexico), Toribio Fernández Otero, Eduardo Rodríguez, Angel Estévez

[Validation of Polymeric artificial muscles with a Proportional- Integral control system](#)

10:50 to 11:10

Coffee Break

ROOMS:		101A	101B		101C		101D	102	103	201AB		201EF	201C	201D
SYMPOSIUM		s05	s18	s07	s14	s04	s01	s03	s09	s03	s08/s11			
08:15 - 09:15		Plenary Lecture: Martin Winter (Plenary Hall)												
09:30 - 09:50	François Béguin	Yann Leroux	Peter Broekmann	Masa-aki Haga	Shengli Chen	Jan Vacek	Yu-Guo Guo	Li-Chyong Chen	Nae-Lih Wu	Yudai Yamamoto				
09:50 - 10:10	Takashi Kakiuchi	Kazuo Kondo	I. A. Rutkowska	Yujia Deng	Guy Denuault	Judith Rishpon	Louise Frenck	Ana Sofia Varela	Laurence Hardwick	Achim W. Hassel				
10:10 - 10:30	Mathieu Salanne	Jeyab. Chinnaya	Wei-Yang Zeng	Kim Daasbjerg	Anthony Kucernak	Tzu-En Lin	Hang Su	Ida Hjorth	Sven Uhlenbruck	En-Hou Han				
10:30 - 10:50	Teresa A. Centeno	Chu-Chi Liu												
10:50 - 11:10		Coffee Break												
11:10 - 11:30		General Assembly 11:10 to 12:10 (Plenary Hall)												
11:30 - 11:50														
11:50 - 12:10														
12:10 - 12:30														
12:30 - 12:50														
12:50 - 13:10		Division 5 Meeting		Division 2 Meeting		Division 3 Meeting		Division 1 Meeting		Division 4 Meeting		Division 7 Meeting		Division 6 Meeting
13:10 - 13:50														
13:50 - 14:00														
14:00 - 14:20	John R. Miller	Alexander Oleinick	Jon Ustarroz	Y. Tateyama	Yu Morimoto	Fethi Bedioui	K. Zaghib	Jun Maruyama	Gao Liu	Flavio Mara				
14:20 - 14:40	Hsisheng Teng	A. Fernández-Ia-V.	Philip Bartlett	Louzhen Fan		Jan Clausmeyer		Yan Shen	Xiaopeng Li					
14:40 - 15:00	Masashi Ishikawa	Ying Wan	Lu Chen	Xingxing Chen	Kuan-Wen Wang	Yu-Chen Chang	Kisuk Kang	Sho Fujita	Hiroyuki Usui	Dongil Lee				
15:00 - 15:20	Patrice Simon	Conchi Ania	Tso-Fu Mark Chang	A. Minguzzi	Tilman Jurzinsky	Angelika Holzinger	Reinhold Koch	Xi Cheng	Qihui Wu	M. F. Guedes da S.				
15:20 - 15:40	Indrek Tallo	Maria Cuartero	Jinqiu Zhang	J. Rodriguez-Lop.	Sayoko Shironita	Ahmed Abdo	Michael Palmer	Wenting Xu	Yingshun Li	Eric Labbe				
15:40 - 16:00	Masayuki Morita	S. Moraes Silva	Zenglin Wang	Michael Holzinger	Evgeniy Gribov	Patrick Unwin	Jagabandhu Patra	Juan Manriquez	Selina Tillmann	James Y. Becker				
16:00 - 16:20	Juhan Lee	Jen-Yuan Wang	Chiao-Chien Wei		Fen Guo		Ji Su Chae	Ruud Kortlever	Leiting Zhang	Zhifeng Ding				
16:20 - 16:40		Coffee Break												
16:40 - 17:00	Chi-Chang Hu	A. Gomis-Bereng.	Ryoichi Aogaki	Giovanni Valenti	Jianguo Liu	Raymond Wong	Chun-Ting Li	Peng Bai	Kazuhiro Chiba					
17:00 - 17:20	Panel Discussion about Novel Insights to Electrochemical Capacitors	Leigh Aldous	Po-Fan Chan	Kristina Tschulik	Byungchan Bae	Gunther Wittstock	O. S. Mendoza-H.	Fabio Dionigi	Edgar Ventosa					
17:20 - 17:40		Dan Nguyen Dang	Iwao Mogi	Line Koefoed	Kwong-Yu Chan	Jie Zhang	Hai-Jung Peng	C. M. Sanchez-S.	Jee-Jay Chen	Jingxian Yu				
17:40 - 18:00		Zhang Dalei	Alex. Vaskevich	Stefania Rapino	Michael Eikerling	Yi-Tao Long	Xiaoyu Liu	L. Tamasauskaite	Georgios Nikiforidis	Chengchu Zeng				
18:00 - 18:20		Miikka Jokinen	Yao-Lin Tsai	M. A. Vorotyntsev	S. Shanmugam	Jung-Chi Wang	Han Wang	Luis F. Arenas	Jiri Ludvik	Wenrong Yang				
18:20 - 18:40				S. Cordoba de Tor.										
19:00		Banquet												

# Thursday, 8 October 2015 - Morning

---

## Plenary Lecture

**Room : Plenary Hall**

*Chaired by:* Nae-Lih Wu

08:15 to 09:15

**Martin Winter** (MEET Battery Research Center/Institute of Physical Chemistry, University of Muenster/Helmholtz Institute Muenster HI MS, Muenster, Germany), Dennis Gallus, Ralf Wagner, Marius Amereller, Johannes Kasnatscheew, Elisabeth Kraemer, Steffen Krueger, Xin Qi, Ji Lie, Isidora Cekic-Laskovic

[Neglected, Forgotten or Unimportant? Inactive Materials in Lithium Ion Batteries](#)

---

## Symposium 1: New Directions in Analytical Electrochemistry

**Room : 103**

*Chaired by:* Fethi Bedioui and Gunther Wittstock

09:30 to 10:10 Keynote **Early Career Analytical Electrochemistry Prize of ISE Division 1**

**Jan Vacek** (Department of Medical Chemistry and Biochemistry, Palacky University, Olomouc, Czech Republic)

[Electrochemistry of Membrane Proteins](#)

10:10 to 10:30

**Judith Rishpon** (Molecular Microbiology and Biotechnology, Tel-Aviv University, Tel-Aviv, Israel)

[Combined Tyrosinase \(A Multi-Potent Enzyme\) and Electrodes Modified with nanoparticles for Fast and Highly Sensitive Environmental Monitoring and Medical Diagnostics](#)

10:30 to 10:50

**Tzu-En Lin** (Chemistry and Chemical Engineering, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland), Fernando Cortés-Salazar, Andreas Lesch, Alexandra Bondarenko, Hubert Girault

[Cancer Stage Identification by Scanning Electrochemical Microscopy: Investigation of Tyrosinase inside Melanoma Tissues](#)

10:50 to 11:10

Coffee Break

---

## Symposium 3: Batteries for Tomorrow's World

---

**Room : 201AB**

*Chaired by:* Claude Delmas

### 09:30 to 10:10 Keynote **Tajima Prize**

**Yu-Guo Guo** (Institute of Chemistry, Chinese Academy of Sciences (CAS), Beijing, China)

[Advanced Cathodes and Metallic Anodes for Next-Generation Rechargeable Batteries](#)

10:10 to 10:30

**Louise Frenck** (Environmental Energy Technologies Division, Lawrence Berkeley National Laboratory, Berkeley, USA), Renaud Bouchet, Philippe Stevens, Nitash Balsara

[Study of ceramic-polymer/lithium interface for lithium air batteries](#)

10:30 to 10:50

**Hang Su** (College of Energy & School of Energy Research, Xiamen University, Xiamen, China)

[Hierarchical Mn<sub>2</sub>O<sub>3</sub> Hollow Microspheres of high performance as Anode of LIBs and XANES studies of Conversion Reaction Mechanism](#)

10:50 to 11:10

Coffee Break

---

## Symposium 3: Batteries for Tomorrow's World

---

**Room : 201C**

*Chaired by:* Yong Joon Park

09:30 to 09:50 Invited

**Nae-Lih WU** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Fu-Sheng Li, Yu-Shiang Wu, Jacky Chou, Martin Winter

[Research on Polymeric Artificial Solid-Electrolyte-Interphase for Enhanced Performance of Li-ion Battery Anodes](#)

09:50 to 10:10 Invited

**Laurence Hardwick** (Chemistry, University of Liverpool, Liverpool, United Kingdom), Vivek Padmanabhan, Richard Nichols

[In situ infrared spectroscopy on gold substrates to track film formation and intermediates in Li-ion and Li-air electrolytes](#)

10:10 to 10:30

**Sven Uhlenbruck** (Institute of Energy and Climate Research (IEK-1), Forschungszentrum Jülich GmbH, Jülich, Germany), Hans-Gregor Gehrke, Sandra Lobe, Chih-Long Tsai, Christian Dellen, Aiko Bünting, Martin Bitzer, Jürgen Dornseiffer, Tim Van Gestel, Olivier Guillon

[Manufacturing and Performance of solid-state thin-film batteries](#)

10:50 to 11:10

Coffee Break

## Symposium 4: Advances in Fuel Cells from Materials to Systems

Room : 102

Chaired by: Shengli Chen

09:30 to 09:50 Invited

**Shengli Chen** (Chemistry Department, Wuhan University, Wuhan, China), Junxiang Chen, Yuwen Liu

[Nature of Active Sites and Origin of Large Overpotential of the Oxygen Reduction Reaction on Pt\(111\) Surface](#)

09:50 to 10:10

**Yujia Deng** (Department of Chemistry, University of Copenhagen, Copenhagen, Denmark), Matthias Arenz, Gustav K.H. Wiberg

[The Steady State coverage of oxygenated species on Platinum and its influence on the Oxygen Reduction and Hydrogen Oxidation Reaction in acid electrolyte](#)

10:10 to 10:30

**Guy Denuault** (Chemistry, University of Southampton, Southampton, United Kingdom), Samuel Perry

[Amperometric Study of the Oxygen Reduction Reaction on Oxide Free Metals: Evidence for the Reduction of Pre-adsorbed Dioxide and its Dependence on the Metal Substrate](#)

10:30 to 10:50

**Anthony Kucernak** (Chemistry, Imperial College London, London, United Kingdom), Matthew Markiewicz, Christopher Zalitis, Christopher Zalitis, Matthew Markiewicz

[Is the Tafel approximation sufficient to predict electrocatalyst performance in polymer electrolyte fuel cells?](#)

10:50 to 11:10

Coffee Break

## Symposium 5: Novel Insights to Electrochemical Capacitors

Room : 101A

Chaired by: Frédéric Favier

09:30 to 10:10 Keynote

**François Béguin** (Institute of Chemistry and Technical Electrochemistry, Poznan University of Technology, Poznan, Poland), Patryk Przygocki, Qamar Abbas, Paula Ratajczak

[The aqueous electrochemical capacitor: a high energy alternative solution to organic electrolyte-based systems](#)

10:10 to 10:30 Invited

**Mathieu Salanne** (Laboratoire PHENIX / Maison de la Simulation, UPMC / CNRS, Paris, France), Clarisse Pean, Celine Merlet, Benjamin Rotenberg, Paul Madden, Pierre-Louis Taberna, Barbara Daffos, Patrice Simon, Yury Gogotsi, Matthieu Haefele, David Limmer, David Chandler

[The Electric Double Layer has a Life of its Own](#)

10:30 to 10:50 Invited

**Teresa A. Centeno** (Coal, Science and Environment, Instituto Nacional del Carbón-CSIC, Oviedo, Spain), Belén Lobato, Gelines Moreno-Fernández, Andrea Balducci

[Physico-Chemical Features of Carbons and their Behavior in Electrochemical Capacitors](#)

10:50 to 11:10

Coffee Break

## Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication

**Room : 101C**

*Chaired by:* Rohan Akolkar and Dow Wei-Ping

09:30 to 09:50 Invited

**Peter Broekmann** (Department of Chemistry and Biochemistry, University of Bern, Bern, Switzerland), Hai Nguyen, Valentine Grimaudo, Pavel Moreno-Garcia, David Lechner, Florian Stricker, Andreas Riedo, Peter Wurz

[Combining Superfill and Leveling Capabilities: New Hybrid Polymers for Advanced Damascene Applications](#)

09:50 to 10:10 Invited

**Kazuo Kondo** (Ch.E., Osaka Prefecture University, Sakai, Japan), Van Ha

[Extremely Fast Filling by V-shape TSV and Cu\(I\)thiolate accumulation](#)

10:10 to 10:30

**Wei-Yang Zeng** (Chemical Engineering, National Chung Hsing University, Taichung, Taiwan), Wei-Ping Dow

[Using Graphene as a Conducting Layer and Barrier Layer for high aspect ratio Through Silicon Via Filling](#)

10:30 to 10:50

**Chu-Chi Liu** (Chemical Engineering, National Chung Hsing University, Taichung, Taiwan), Wei-Ping Dow

[Microvia filling in an Acidic Copper Planting Bath with Insoluble Anodes](#)

10:50 to 11:10

Coffee Break

THURSDAY AM

## Symposium 8: Corrosion and Passivity

**Room : 201D**

*Chaired by:* Koji Fushimi

09:30 to 09:50

**Yudai Yamamoto** (Graduate School of Chemical Sciences and Engineering, Hokkaido University, Sapporo, Japan), Misako Jin, Yuichi Kitagawa, Takayuki Nakanishi, Yasuchika Hasegawa, Koji Fushimi

[Local Measurement of Hydrogen Diffusion in Steel Sheet](#)

09:50 to 10:10 Invited

**Achim Walter Hassel** (CD Laboratory COMBOX, Johannes Kepler University Linz, Linz, Austria)

[Corrosion studies using non radioactive isotopes of H, Zn and Fe](#)

10:10 to 10:50 Keynote

**En-Hou Han** (Institute of Metal Research, Chinese Academy of Sciences, Shenyang, China), En-Hou Han, Jianqiu Wang, Xinqiang Wu, Zhiming Zhang

[Corrosion Electrochemistry and Surface Film Properties of Alloy 690 in High Temperature Pressurized Water](#)

10:50 to 11:10

Coffee Break

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 201EF**

*Chaired by:* Chen-Hao Wang and Lin Zhuang

09:30 to 10:10 Keynote

**Li-Chyong Chen** (Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan), Kuei-Hsien Chen, Hsin-Cheng Hsu, He-yun Du, Indrajit Shown, Hsin-Chih Huang, Yu-Chung Chang, Chen-Hao Wang, Sung-Tung Chang

[Macrocyclics, Graphene Oxides-based Nano-catalysts, and Related Hybrids for Fuel Cells and Solar Fuels](#)

10:10 to 10:30

**Ana Sofia Varela** (Chemical Engineering, TU-Berlin, Berlin, Germany), Wen Ju, Peter Strasser

[CO<sub>2</sub> Electroreduction on Heteroatom-doped Carbon Catalyst](#)

10:30 to 10:50

**Ida Hjorth** (Chemical Engineering, Norwegian University of Technology and Science, Trondheim, Norway), Navaneethan Muthuswamy, De Chen

[Effects from modifying carbon nanofiber supports on metal nanoparticle catalyzed CO<sub>2</sub> reduction](#)

10:50 to 11:10

Coffee Break

---

## Symposium 14: Modeling, Design and Characterization of Nanostructured, Electroactive and Multifunctional Materials

---

**Room : 101D**

*Chaired by:* Michael Holzinger

09:30 to 09:50

**Masa-aki Haga** (Department of Applied Chemistry, Chuo University, 1-13-27 Ksuga, Bunkyo-ku, Japan), Hiroaki Ozawa, Takumi Nagashima

[Photoelectrochemical Response of Hetero-layer Films Composed of Redox-active Ru Complexes: Charge Trapping and Memory Effect](#)

09:50 to 10:10

**Iwona A. Rutkowska** (Department of Chemistry, University of Warsaw, Warsaw, Poland), Pawel J. Kulesza

[Development of Multifunctional Materials Composed of Selected Noble Metal and Metal Oxide Nanostructures for Efficient Electrocatalytic Oxidation of Small Organic Molecules](#)

10:10 to 10:50 Keynote

**Kim Daasbjerg** (Department of Chemistry, Aarhus University, Aarhus, Denmark)

[Novel Hybrid Materials Prepared from Polymer Brushes and Graphene](#)

10:50 to 11:10

Coffee Break

---

## Symposium 18: General Session

---

**Room : 101B**

*Chaired by:* Juan M. Feliu

09:30 to 09:50

**Yann Leroux** (Institut des Sciences Chimiques de Rennes, CNRS - Université de Rennes 1, Rennes Cedex, France), Sébastien Lhenry, Christophe Orain, Françoise Conan, Nathalie Cosquer, Nicolas Le Poul, Yves Le mest, Olivia Reinaud, Philippe Hapiot

[Locally Self-induced “electro-click” onto self-assembled monolayer: Evidence for surface self-catalysis propagation.](#)

09:50 to 10:10

**Takashi Kakiuchi** (Department of Chemistry of Functional Molecules, Konan University, Kobe, Japan), Masahiro Yamamoto

[Single ion activity, pH, liquid junction potential, and the essence of electrochemistry: in response to “A pH centenary” by Robert de Levie](#)

10:10 to 10:30

**Jeyabharathi Chinnaya** (Institute of Biochemistry, University of Greifswald, Greifswald, Germany), Paula Ahrens, Ulrich Hasse, Fritz Scholz

[Does a link between multiple oxidation peaks of gold oxide formation and exposed crystal planes exist on polycrystalline gold?](#)

10:50 to 11:10

Coffee Break

# Thursday, 8 October 2015 - Afternoon

## Symposium 1: New Directions in Analytical Electrochemistry

Room : 103

Chaired by: Sabine Szunerits; Jan Vacek

14:00 to 14:20

**Fethi Bedioui** (CNRS UTCBS 8258-Chimie ParisTech, Chimie ParisTech, Paris, France), Gonzalo Ramirez, Sophie Griveau, Minerva Alvaro, Silvia Gutierrez-Granados

[In Vivo Electrochemical Assessment of Possible Melatonin Effect on Nitric Oxide Production From Kidneys of Sub-Acute Lead Treated Rats](#)

14:20 to 14:40

**Jan Clausmeyer** (Analytische Chemie, Center for Electrochemical Sciences, Ruhr-Universität Bochum, Bochum, Germany), Yanjun Zhang, Miriam Marquitan, Ainara López Córdoba, Yuri Korchev, Wolfgang Schuhmann

[Amperometric Nanosensors and Field-Effect Transistors for Extra- and Intracellular Chemical Analysis](#)

14:40 to 15:00

**Yu-Chen Chang** (Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Yi-Ting Chen, Guan-Lin Chen, Kuo-Chuan Ho, Wei-Hung Chiang

[Controllable Synthesis of Heteroatom-Doped Carbon Nanotubes under Atmospheric Pressure and Their Electrocatalytic Ability to L-cysteine](#)

15:00 to 15:20

**Angelika Holzinger** (Institute of Analytical and Bioanalytical Chemistry, University Ulm, Ulm, Germany), Peter Knittel, Jong Seok Moon, Christine Kranz

[AFM Tip-integrated Antimony Electrodes for pH Detection](#)

15:20 to 15:40

**Ahmed (Galal) Abdo** (Department of Chemistry, Faculty of Science - Kuwait University, Kuwait, Kuwait), Ekram El-Ads, Asmaa Ibrahim, Youssuf Mohamed, Nada Atta

[Electrochemistry and Determination of Some Biomedical and Biological Molecules at Carbon –Based Ionic Liquid Crystals Composite Electrodes](#)

15:40 to 16:00 Invited

**Patrick Unwin** (Department of Chemistry, University of Warwick, Coventry, United Kingdom)

[Making Movies: Next Generation Electrochemical Imaging](#)

16:20 to 16:40

Coffee Break

16:40 to 17:20 Keynote

**Gunther Wittstock** (Department of Chemistry, Carl von Ossietzky University of Oldenburg, Oldenburg, Germany), Heinz Bültel, Fabian Peters, Julian Schwenzel, Patrick Schwager, Daniela Fenske

[Microelectrochemical in situ observation of battery electrodes](#)

17:20 to 17:40 Invited

**Jie Zhang** (Chemistry, Monash University, Melbourne, Australia), Kiran Bano, Si-Xuan Guo, Alan Bond

[Determination of Fast Electrode Kinetics Using Fourier Transformed Large Amplitude AC Voltammetry](#)

17:40 to 18:00

**Yi-Tao Long** (Department of Chemistry, East China University of Science and Technology, Shanghai, China)

[Ubiquinones: understanding electrochemistry from solution to surface](#)

## Symposium 3: Batteries for Tomorrow's World

Room : 201AB

Chaired by: Takeshi Abe

14:00 to 14:40 Keynote

**K. Zaghib** (Institut de Recherche d'Hydro-Québec, Varennes, Canada), P. Hovington, M. Lagacé, A. Guerfi, P. Bouchard, A. Mauger, C. M. Julien, M. Armand

[New Lithium Metal Polymer Solid State Battery for an Ultrahigh Energy: Nano C-LiFePO<sub>4</sub> versus Nano Li<sub>1.2</sub>V<sub>3</sub>O<sub>8</sub>](#)

14:40 to 15:00 Invited

**Kisuk Kang** (Department of Materials Science and Engineering, Seoul National University, Seoul, Korea), Kyu-Young Park

[Olivine with zero anti-site defect and three dimensional lithium diffusion paths](#)

15:00 to 15:20

**Reinhold Koch** (RP06, TUM Create Ltd., Singapore, Singapore), Andreas Jossen

[On the Influence of Mechanical Compression on the Impedance of Aged LiFePO<sub>4</sub> - Graphite Cells](#)

15:20 to 15:40

**Michael Palmer** (Chemistry, University Of Southampton, Southampton, United Kingdom), John R. Owen, Andrew Hector

[In-situ XRD of High Voltage Lithium Insertion Electrodes](#)

15:40 to 16:00

**Jagabandhu Patra** (Institute of Materials Science & Engineering, National Central University, Taoyuan, Taiwan), Prem Prakash Dahiya, Jason Fang, Yu-Wei Lin, Chung-Jen Tseng, S. Basu, S. B. Majumder, Jeng-Kuei Chang

[Electrochemical Performance of 0.5Li<sub>2</sub>MnO<sub>3</sub>-0.5Li\(Mn<sub>0.375</sub>Ni<sub>0.375</sub>Co<sub>0.25</sub>\)O<sub>2</sub> Composite Cathode Using Pyrrolidinium-based Ionic Liquid Electrolytes](#)

16:00 to 16:20

**Ji Su Chae** (Energy & Environmental Division, Korea Institute of Ceramic Engineering & Technology, Jinju-si, Korea), Sun-Min Park, Won-Sub Yoon

[Understanding the Improved Electrochemical Properties of Li<sub>2</sub>O-2B<sub>2</sub>O<sub>3</sub> Coated LiNi<sub>0.5</sub>Mn<sub>1.5</sub>O<sub>4</sub> for Lithium-ion Batteries](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Raymond Wong** (Byon Initiative Research Unit, RIKEN, Wako, Japan), Hye Ryung Byon

[The Role of Defects and Oxygen Functionalities in Carbon Nanotube-based electrodes for the Lithium-oxygen Battery](#)

17:00 to 17:20

**Omar Samuel Mendoza-Hernandez** (Department of Materials Science and Technology, Nagaoka University of Technology, Nagaoka, Japan), Shuichi Taniguchi, Yuki Maruyama, Hiroaki Ishikawa, Yoshitsugu Sone, Minoru Umeda

[Thermal Runaway Behavior of 18650 Li-ion Cells Before and After Storage Degradation at High Temperature](#)

17:20 to 17:40

**Hai-Jung Peng** (Electrochemical Energy Storage Section, Paul Scherrer Institute, Villigen PSI, Switzerland), Sigita Urbonaitė, Claire Villevieille, Hannes Wolf, Klaus Leitner, Petr Novak

[Consequences of Electrolyte Degradation for the Electrochemical Performance of NCM Battery Materials](#)

17:40 to 18:00

**Xiaoyu Liu** (Chemistry Department, Fudan University, Shanghai, China)

[Surface phase transformation and CaF<sub>2</sub> coating for enhanced electrochemical performance of Li-rich Mn-based Cathodes](#)

18:00 to 18:20

**Jung-Chi Wang** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan), Fu-Ming Wang

[Forward and reverse differential-pulse applied in the formation of solid electrolyte interface with constant temperature addition in lithium ion battery](#)

## Symposium 3: Batteries for Tomorrow's World

**Room : 201C**

*Chaired by:* T. Richard Jow

14:00 to 14:20 Invited

**Gao Liu** (Energy Storage and Distributed Resources Division, Lawrence Berkeley National Laboratory, Berkeley, USA), Hui Zhao, Zhe Jia, Sang-Jae Park

[Functional Conductive Polymer Binders Enabled High-stability Cycling of Alloy Anodes](#)

14:20 to 14:40

**Xiaopeng Li** (Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany), Ralf Wehrspohn

[High performance mesoporous metallurgical silicon nanowire anode for lithium ion batteries](#)

14:40 to 15:00

**Hiroyuki Usui** (Graduate School of Engineering, Tottori University, Tottori, Japan), Masahito Nomura, Hiroki Nishino, Masatoshi Kusatsu, Tadatoshi Murota, Hiroki Sakaguchi

[Gadolinium silicide/silicon composite anode for next-generation lithium-ion battery](#)

15:00 to 15:20

**Qihui Wu** (Chemistry, Quanzhou Normal University, Quanzhou, China)

[Ge@GeO<sub>2</sub> core@shell nanoparticles/multi-layer carbon composites as anode materials for lithium-ion batteries](#)

15:20 to 15:40

**Yingshun Li** (School of Energy and Environment, City University of Hong Kong, Hong Kong, China), Jieqing He, Hui Zhou, Wenpei Kang, Denis Y. W. Yu

[Enhancing cycling stability of tin dioxide anode for lithium-ion batteries with a stretchable polyimide matrix](#)

15:40 to 16:00

**Selina Tillmann** (MEET Battery Research Center, University of Muenster, Muenster, Germany), Daniel Hermida Merino, Martin Winter, Isidora Cekic-Laskovic, Katja Loos

[Block Copolymer-Templates for the Design of Three-Dimensional Interpenetrating Current Collectors for Submicrostructured Electrodes](#)

16:00 to 16:20

**Leiting Zhang** (Department of Chemical and Biomolecular Engineering, The Hong Kong University of Science and Technology, Hong Kong, China), Jean-Marie Tarascon, Guohua Chen

[Impact of Relative Humidity on Sulfate-based Cathode Materials](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 **Oronzio and Niccolò De Nora Foundation Young Author Prize**

**Peng Bai** (Chemical Engineering, Massachusetts Institute of Technology, Cambridge, USA), Martin Z. Bazant

[A Solid-Electrolyte-Enabled Lithium-Bromine Flow Battery](#)

17:00 to 17:20

**Edgar Ventosa** (Department of Analytical Chemistry, University of Bochum, Bochum, Germany), Cristina Flox, Joan Ramon Morante, Wolfgang Schuhmann

[Semi-solid flow battery: an emerging electrochemical system](#)

17:20 to 17:40

**Jee-Jay Chen** (Chemical Engineering, University of Michigan - Ann Arbor, Ann Arbor, USA), Mark Barteau  
[Polyoxometalates for Non-aqueous Redox Flow Battery Applications](#)

17:40 to 18:00

**Georgios Nikiforidis** (Byon Initiative Research Unit (IRU), RIKEN, Wako, Japan), Hye Ryung Byon  
[Improvements in the aqueous lithium-iodine battery](#)

18:00 to 18:20

**Luis F. Arenas** (Faculty of Engineering and the Environment, University of Southampton, Southampton, United Kingdom), Carlos Ponce de Leon, Frank C. Walsh  
[Advances on the Zinc-Cerium Redox Flow Battery for Energy Storage](#)

---

## Symposium 4: Advances in Fuel Cells from Materials to Systems

---

**Room : 102**

*Chaired by:* Byungchan Bae and Yu Morimoto

14:00 to 14:40 Keynote

**Yu Morimoto** (Sustainable Energy & Environment Dept., Toyota Central R&D Labs., Inc., Nagakute, Japan), Masanori Inaba, Shuhei Yoshino, Masao Shibata, Tatsuya Hatanaka  
[Alternative PEFC Catalysts for Future Commercial FCVs](#)

14:40 to 15:00

**Kuan-Wen Wang** (Institute of Materials Science and Engineering, National Central University, Taoyuan, Taiwan), Jeng-Han Wang, Yu-Ting Liang  
[The Performance and Stability of the Oxygen Reduction Reaction on Pt/Vbased Nanorods: An Experimental and Computational Study](#)

15:00 to 15:20

**Tilman Jurzinsky** (Applied Electrochemistry, Fraunhofer Institute for Chemical Technology, Pfaffzettel, Germany), Carsten Cremers, Karsten Pinkwart, Jens Tübke  
[A DEMS Study on the Influence of Ag Add-Atoms on Pd-based Catalysts for Methanol Oxidation in Alkaline Environment](#)

15:20 to 15:40

**Sayoko Shironita** (Department of Materials Science and Technology, Nagaoka University of Technology, Nagaoka, Japan), Kazutaka Sato, Kazuma Yoshitake, Minoru Umeda  
[Pt-Ru/C Anode Performance of Polymer Electrolyte Fuel Cell under Carbon Dioxide Atmosphere](#)

15:40 to 16:00

**Evgeniy Gribov** (Group of Adsorption & catalytic processes for fuel cells, Boreskov Institute of Catalysis, Novosibirsk, Russia), Aleksey Kuznetsov, Viktor Golovin, Dmitriy Krasnikov, Vladimir Kuznetsov, Aleksey Okunev  
[The Oxygen Electroreduction Reaction Performance of Pt Catalysts Supported on Commercial Blacks and Nanostructured Carbons: Multiwall Nanotubes and Nanofibers](#)

16:00 to 16:20

**Fen Guo** (College of Materials Science and Chemical Engineering, Harbin Engineering University, Harbin, China), Dianxue Cao, Ke Ye, Kui Cheng, Mengmeng Du, Dongming Zhang  
[Preparation of Ni-Co Nanowire Arrays Anode Electrocatalyst and the Performance of Direct Urea-Hydrogen Peroxide Fuel Cell](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Jianguo Liu** (College of Engineering and Applied Sciences, Nanjing University, Nanjing, China), Jin Xie, Zhigang Zou

[Well-ordered Ru@Pt Core-shell Nanocatalysts with Tunable Composition and Enhanced Electrocatalytic Properties](#)

17:00 to 17:20

**Byungchan Bae** (Fuel Cell Laboratory, Korea Institute of Energy Research, Yuseong-gu, Daejeon, Korea)

[Development of Sulfonated Poly\(Arylene Ether Sulfone\) Multi-Block Membranes for PEMFC Application](#)

17:20 to 17:40

**Kwong-Yu Chan** (Department of Chemistry, The University of Hong Kong, Pokfulam Road, Hong Kong, China)

[Ion Exchange Polymer Threaded in MOF as a Potential Electrolyte with Fast Exchange and High Selectivity](#)

17:40 to 18:00

**Michael Eikerling** (Department of Chemistry, Simon Fraser University, Burnaby, Canada), Mahdi Ghelichi, Pierre-Eric Alix Melchy

[Modeling of Structure Formation and Fracturing in Polymer Electrolyte Membranes](#)

18:00 to 18:20

**Sangaraju Shanmugam** (Energy Systems Eng, DGIST, Daegu, Korea), Kriangsak Ketpang

[Development of Composite Electrolyte Membranes for Polymer Electrolyte Fuel cells Operating at Low Humidity](#)

---

## Symposium 5: Novel Insights to Electrochemical Capacitors

---

**Room : 101A**

*Chaired by:* Thierry Brousse, François Béguin, Daniel Bélanger and Teresa A. Centeno

14:00 to 14:20 Invited

**John R. Miller** (JME, Inc. and Case Western Reserve University, JME, Inc. and Case Western Reserve University, Beachwood, USA)

[Valuing Electrochemical Capacitor Technology](#)

14:20 to 14:40

**Hsisheng Teng** (Chemical Engineering, National Cheng Kung University, Tainan, Taiwan), Wei Hsieh, Hsin-Chieh Huang

[Facile Simulation of Electric Double-Layer Capacitance Based on Helmholtz Models](#)

14:40 to 15:00 Invited

**Masashi Ishikawa** (Chemistry and Materials Engineering, Kansai University, Japan), Masaki Yamagata

[Advanced Auxiliary Materials in EDLC for Enhancing Power and Energy](#)

15:00 to 15:20 Invited

**Patrice Simon** (CIRIMAT, Université Paul Sabatier, Toulouse, France), Barbara Daffos, Wan Yu Tsai, Peihua Huang, Kevin Brousse, Pierre-Louis Taberna

[Recent advances on the understanding of ion adsorption/transfer in nanoporous carbon electrodes: application to supercapacitors](#)

15:20 to 15:40

**Indrek Tallo** (Institute of Chemistry, University of Tartu, Tartu, Estonia), Ester Tee, Enn Lust, Thomas Thomberg, Heisi Kurig, Alar Jänes

[Surprisingly Large Improvements in SiC-CDC Based EDLC via Simple CO<sub>2</sub> Activation Method](#)

15:40 to 16:00 Invited

**Masayuki Morita** (Department of Applied Chemistry, Graduate School of Science, Yamaguchi University, Ube, Japan), Takuma Izumi, Yuya Noguchi, Masahiro Tokita, Kenta Fujii, Nobuko Yoshimoto

[Influences of Residual Water in Porous Carbon Electrodes on Their Cycling Behavior in Organic Electrolyte Solutions](#)

16:00 to 16:20

**Juhan Lee** (Energy Materials Group, INM - Leibniz Institute for New Materials, Saarbruecken, Germany), Daniel Weingarth, Volker Presser

[Hybrid capacitors for moderate energy storage and high power applications: double layer formation and soluble redox couples](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Chi-Chang Hu** (Department of Chemical Engineering, National Tsing Hua University, Hsinchu, Taiwan), Arturas Adomkevicius, Shin-Ming Li, Tzu-Man Ou

[Preparation and characterization of Mn oxide-based composites for high-performance asymmetric supercapacitors](#)

17:00 to 18:20

**Panel Discussion about Novel Insights to Electrochemical Capacitors**

---

## Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication

---

**Room : 101C**

*Chaired by:* Alexander Vaskevich

14:00 to 14:20

**Jon Ustarroz** (Electrochemical and Surface Engineering (SURF), Vrije Universiteit Brussel, Brussels, Belgium), El Amine Mernissi Cherigui, Bart Geboes, Kadir Sentosun, Pieter Bouckennoog, Herman Terryn, Sara Bals, Tom Breugelmans, Annick Hubin

[Electrodeposition of Electrocatalytic Nanostructures from Aqueous Solutions and Deep Eutectic Solvents: Aggregative Growth](#)

14:20 to 14:40

**Philip Bartlett** (Chemistry, University of Southampton, Southampton, United Kingdom)

[Electrodeposition of Nanowires and Nanostructures from Supercritical Fluids](#)

14:40 to 15:00

**Lu Chen** (Chemistry Department, Monash University, Melbourne, Australia), Mike Horne, Alan Bond, Jie Zhang

[Room Temperature Electrodeposition of Metallic Magnesium from Ethylmagnesiumbromide/Tetrahydrofuran and Ionic Liquid Mixtures](#)

15:00 to 15:20 Invited

**Tso-Fu Mark Chang** (Precision and Intelligence Laboratory, Tokyo Institute of Technology, Yokohama, Japan), Wei-Hao Lin, Chun-Yi Chen, Yung-Jung Hsu, Chi-Chang Hu, Tatsuo Sato, Masato Sone

[Conducting Electrochemical Deposition Reactions in Supercritical Carbon Dioxide Emulsified Electrolyte](#)

15:20 to 15:40

**Jinqiu Zhang** (School of Chemical Engineering and Technology, Harbin Institute of Technology, Harbin, China), Xing Gu, Peixia Yang, Maozhong An

[Electrodeposition Process of Ni-Ga Bimetallic Catalyst in BMIm-OTf Ionic Liquid Electrolyte](#)

15:40 to 16:00

**Zenglin Wang** (School of Chemistry and Chemical Engineering, Shaanxi Normal University, Xi'an, China),  
Shaojun Ren, Zhanwu Lei

[Investigation Nitrogen Heterocyclic Compounds as Levelers for Electroplating Cu Filling by Electrochemical Method and Quantum Chemical Calculation](#)

16:00 to 16:20

**Chiao-Chien Wei** (Wet Deposition, BASF AP, Taoyuan, Taiwan), Eric Chou, Shih-Ming Lin, Steve Shih

[Bottom-up Filling of Damascene Trenches with Cobalt by Electroplating Process](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Ryoichi Aogaki** (Electronic Engineering, Polytechnic University, Tokyo, Japan), Ryoichi Morimoto, Miki Asanuma, Iwao Mogi, Atushi Sugiyama, Makoto Miura, Yoshinobu Oshikiri, Yusuke Yamauchi

[Chloride Effect on Chiral Catalytic Activity in Magneto-electrodeposition](#)

17:00 to 17:20

**Po-Fan Chan** (Chemical Engineering, National Chung Hsing University, Taichung, Taiwan), Wei-Ping Dow

[The Spontaneous Potential Oscillations in a Galvanostatic Copper Electrodeposition](#)

17:20 to 17:40

**Iwao Mogi** (Institute for Materials Research, Tohoku University, Sendai, Japan), Ryoichi Aogaki, Kazuo Watanabe

[Chirality Induction by Galvanostatic Magneto-electrodeposition](#)

17:40 to 18:00

**Alexander Vaskevich** (Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel), Mariano Susman, Israel Rubinstein

[Chemical Deposition and Galvanic Replacement of Morphologically Controlled Cu<sub>2</sub>O Nanoparticle Films](#)

18:00 to 18:20

**Yao-Lin Tsai** (Chemical Engineering, National Chung Hsing University, Taichung, Taiwan), Wei-Ping Dow

[Using Cu Nanoparticles as Catalysts of Electroless Copper Deposition for Metallization of a Printed Circuit Board](#)

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 201EF**

*Chaired by:* Fabio Dionigi, Anthony Kucernak, Jun Maruyama and Yan Shen

14:00 to 14:20 Invited

**Jun Maruyama** (Environmental Technology Research Division, Osaka Municipal Technical Research Institute, Osaka, Japan), Tsutomu Shinagawa

[Catalyst Layer Structures for Enhancement of Redox Reactions of Oxovanadium Ions](#)

14:20 to 14:40

**Yan Shen** (Wuhan National Laboratory for Optoelectronics, HuaZhong University of Science and Technology, Wuhan, China)

[Self-Supported Co<sub>4</sub>FeP Nanosheet Arrays Supported on Carbon Cloth: An Efficient Catalyst for Electrochemical Hydrogen Evolution](#)

14:40 to 15:00

**Sho Fujita** (Chemical and Energy Engineering, Yokohama National University, 240-8501 Yokohama, Japan), Koichi Matsuzawa, Yuji Kohno, Ikuo Nagashima, Yoshio Sunada, Akiyoshi Manabe, Yoshinori Nishiki, Shigenori Mitsushima

[Property of Oxide Film and Activity of Li<sub>x</sub>Ni<sub>2-x</sub>O<sub>2</sub>/Ni Anode for Alkaline Water Electrolysis](#)

15:00 to 15:20

**Xi Cheng** (Electrochemistry Laboratory, Paul Scherrer Institute, Villigen PSI, Switzerland), Emiliana Fabbri, Maarten Nachtegaal, Raphael Haumont, Thomas Justus Schmidt

[Oxygen evolution reaction: correlation between electronic property and OER activity for  \$\text{La}\_{1-x}\text{Sr}\_x\text{CoO}\_3\$  \( \$x=0, 0.2, 0.4, 0.6, 0.8, 1\$ \) perovskite oxides](#)

15:20 to 15:40

**Wenting Xu** (Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway), Geir Martin Haarberg, Svein Sunde

[Electrochemical Performance of Oxygen Evolving Anodes in Sulphate Electrolyte for Copper Electrowinning](#)

15:40 to 16:00

**Juan Manriquez** (Department of Research, Cideteq, Pedro Escobedo, Mexico)

[Electrocatalytic oxidation of urea on Ni\(II\)cyclam-modified nanoparticulate  \$\text{TiO}\_2\$  anodes for promoting the  \$\text{H}\_2\$  evolution on Pt counterelectrodes](#)

16:00 to 16:20

**Ruud Kortlever** (Catalysis and Surface Chemistry, Leiden University, Leiden, Netherlands), Ines Peters, Collin Balemans, Meital Shviro, Youngkook Kwon, David Zitoun, Marc T.M. Koper

[Electrochemical  \$\text{CO}\_2\$  Reduction on Pd-based Bimetallic Catalysts](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00

**Chun-Ting Li** (Chemical Engineering, National Taiwan University, Taipei, Taiwan), Chuan-Pei Lee, I-Ting Chiu, Kuo-Chuan Ho

[Earth Abundant Iron Diselenide Nanorod Arrays as the Flexible Electro-Catalytic Counter Electrode for Dye-Sensitized Solar Cells](#)

17:00 to 17:20

**Fabio Dionigi** (Department of Chemical Engineering, Technische Universität Berlin, Berlin, Germany), Tobias Reier, Zarina Pawolek, Manuel Gliech, Peter Strasser

[Activity and Selectivity of NiFe Layered Double Hydroxide Electrocatalyst for Seawater Electrolysis](#)

17:20 to 17:40

**Carlos M. Sanchez-Sanchez** (Laboratoire Interfaces et Systèmes Electrochimiques (LISE), CNRS UMR8235 - Sorbonne Universités, UPMC Univ Paris 06, Paris, France), Florin A. Hanc-Scherer, Enrique Herrero

[Electrochemical  \$\text{CO}\_2\$  Reduction at Platinum Surface Structured Electrodes in Room Temperature Ionic Liquids](#)

17:40 to 18:00

**Loreta Tamasauskaite-Tamasiunaite** (Department of Catalysis, Center for Physical Sciences and Technology, Vilnius, Lithuania), Ausrine Zabielaite, Svetlana Lichusina, Agne Matuseviciute, Dijana Simkunaite, Algirdas Selskis, Eugenijus Norkus

[Investigation of Hydrazine Oxidation at Co Fiber Structure Decorated with Pt Nanoparticles](#)

18:00 to 18:20

**Han Wang** (Department of Chemistry, Fudan University, Shanghai, China), Han Wang, Wen-Bin Cai

[Pt \(Pd\) Monolayer on Au Formed by One-Pot Chemical Process with Enhanced Electrocatalytic Performance on Ethanol Oxidation](#)

## Symposium 11: New Important Frontiers in Molecular Electrochemistry

**Room : 201D**

*Chaired by:* Chun-hsien Chen, Toshio Fuchigami, Jiri Ludvik and Armando Pombeiro

### 14:00 to 14:40 Keynote **Jaroslav Heyrovsky Prize for Molecular Electrochemistry**

**Flavio Maran** (Chemistry, University of Padova, Padova, Italy)

[Molecular Electrochemistry: from Protons to Electrons, from Molecules to Molecular Nanoclusters](#)

14:40 to 15:00

**Dongil Lee** (Department of Chemistry, Yonsei University, Seoul, Korea)

[Electrochemistry of Atomically Precise Metal Nanoclusters](#)

15:00 to 15:20 Invited

**M. Fátima C. Guedes da Silva** (Centro de Química Estrutural, Instituto Superior Técnico, Universidade de Lisboa, Lisboa, Portugal)

[Electron-transfer Induced Reactions in Ru and Sn Complexes with Biological Activity](#)

15:20 to 15:40

**Eric Labbe** (Departement de Chimie, Ecole Normale Supérieure, Paris, France), Jose de Jesus Cazaes-Marinero, Olivier Buriez, Christian Amatore, Gerard Jaouen, Hui Zhi Shirley Lee, Pascal Pigeon, Siden Top, Weng Kee Leong

[An electrochemical overview of the oxidative chemistry of ferrocenophanic and ruthenocene antiproliferative drugs](#)

15:40 to 16:00

**James Y. Becker** (Chemistry, Ben-Gurion University of the Negev, Beer Sheva, Israel), Tatiana Golub

[The Effect of Ring-Size on the Anodic Oxidation of Cyclic Amides](#)

16:00 to 16:20 Invited

**Zhifeng Ding** (Chemistry, The University of Western Ontario, London, Canada)

[Electrochemiluminescence of Quantum Dots and Clusters](#)

16:20 to 16:40

Coffee Break

16:40 to 17:20 Keynote

**Kazuhiro Chiba** (Applied Biological Science, Tokyo University of Agriculture and Technology, Tokyo, Japan), Takao Shoji, Yohei Okada, Shokaku Kim

[Anodic Synthesis of Unnatural Peptide and Nucleic Acid Derivatives](#)

17:20 to 17:40

**Jingxian Yu** (Department of Chemistry, The University of Adelaide, Adelaide, Australia), John Horsley, Andrew Abell

[Tunable Peptide-Based Molecular Wires: Experimental Evidence and Theoretical Insights](#)

17:40 to 18:00

**Chengchu Zeng** (College of Life-Science & Bioengineering, Beijing University of Technology, Beijing, China), Nanning Lu, Longji Li

[Electrochemically Induced Friedel-Crafts Arylation of Chalcone Epoxides and Enamides by Organic Redox Mediators](#)

18:00 to 18:20

**Jiri Ludvik** (Molecular Electrochemistry, J. Heyrovský Institute of Physical Chemistry ASCR, Prague, Czech Republic), Tomas Mikysek, Hana Kvapilova, Frantisek Josefik

[Oxaborine and Triazaborine Chromophores, Electrochemical and Theoretical Study](#)

18:20 to 18:40

**Wenrong Yang** (School of Life and Environmental Sciences, Deakin University, Waurn Pond, Australia)

[Real-time Electrochemical Monitoring Covalent Bond Formation in Solution via Nanoparticle-Electrode Collisions](#)

## Symposium 14: Modeling, Design and Characterization of Nanostructured, Electroactive and Multifunctional Materials

**Room : 101D**

*Chaired by:* Line Koefoed and Stefania Rapino

14:00 to 14:20 Invited

**Yoshitaka Tateyama** (International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba, Japan), Keisuke Ushirogata, Keitaro Sodeyama, Yukihiro Okuno

[DFT-MD Study on Formation Processes of Solid Electrolyte Interphase at Negative Electrode Interfaces in Lithium-Ion Battery](#)

14:20 to 14:40

**Louzhen Fan** (Department of Chemistry, Beijing Normal University, Beijing, China), Xiaoyun Tan, Ruihua Guo

[Electrochemical Synthesis of Red Fluorescent Graphene Quantum Dots for the Bioimaging Platform](#)

14:40 to 15:00

**Xingxing Chen** (School of Chemical Engineering, University of Science and Technology Liaoning, Anshan, China), Justus Masa, Alexander Botz, Daniela Wintrich, Wolfgang Schuhmann

[Evaluation of Bifunctional Electrocatalysts for Oxygen Reduction and Evolution by Means of Scanning Electrochemical Microscopy \(SECM\)](#)

15:00 to 15:20

**Alessandro Minguzzi** (Dipartimento di Chimica, Università degli Studi di Milano, Milan, Italy), Elisabetta Achilli, Francesco D'Acapito, Alberto Naldoni, Francesco Malara, Cristina Locatelli, Alberto Vertova, Paolo Ghigna

[Observation of Charge Transfer Cascade in  \$\alpha\$ -Fe<sub>2</sub>O<sub>3</sub>/IrO<sub>2</sub> Photoanodes by In-Operando X-Rays Absorption Spectroscopy](#)

15:20 to 15:40

**Joaquin Rodriguez-Lopez** (Department of Chemistry, University of Illinois at Urbana-Champaign, Urbana, USA), Jingshu Hui, Richa Bhargava, Xuan Zhou, Adam J. Chinderle

[The Impact of Short-Range Electronic Interactions on the Electrochemical Activity of Single- and Few-Layer Graphene](#)

15:40 to 16:20 Keynote

**Michael Holzinger** (Département de Chimie Moléculaire (DCM), University of Grenoble Alpes - CNRS, Grenoble, France)

[Graphene and Carbon Nanotubes for Bioelectrochemical applications](#)

16:20 to 16:40

Coffee Break

16:40 to 17:00 Invited

**Giovanni Valenti** (Chemistry G. Ciamician, University of Bologna, Bologna, Italy), Alessandro Boni, Tiziano Montini, Massimo Marcaccio, Stefania Rapino, Paolo Fornasiero, Maurizio Prato, Francesco Paolucci

[Co-axial Nanostructures for CO<sub>2</sub> Conversion: Synergic Effects between Carbon Nanotubes and Metal Oxides](#)

17:00 to 17:20

**Kristina Tschulik** (Chemistry, University of Oxford, Oxford, United Kingdom), Richard Compton

[Nano-Impacts – Studying Magnetic Field Effects on Single Magnetite Nanoparticles in Solution](#)

17:20 to 17:40

**Line Koefoed** (Department of Chemistry and iNANO, Aarhus University, Aarhus C, Denmark), Kyoko Shimizu, Steen Uttrup Pedersen, Kim Daasbjerg, Alexander Kuhn, Dodzi Zigah

[Simultaneous Covalent Assembling of Two Different Organic Films on Glassy Carbon Using Bipolar Electrochemistry](#)

17:40 to 18:00

**Stefania Rapino** (Department of Chemistry G. Ciamician, University of Bologna, Bologna, Italy), Emanuele Treossi, Vincenzo Palermo, Massimo Marcaccio, Francesco Zerbetto, Francesco Paolucci

[Scanning Electrochemical Microscopy for Probing the Properties of 2D Materials](#)

18:00 to 18:20

**Mikhail A. Vorotyntsev** (Chemistry Department, D. Mendeleev University of Chemical Technology of Russia, Moscow, Russia), Dmitry V. Konev, Olga I. Istakova, Olga A. Sereda, Maria A. Chamraeva, Charles H. Devillers

[Spectroelectrochemistry in the Course of Oxidative Electrolysis as a Tool to Determine the Molecular Structure of Electroactive Polymer Based on Mg\(II\) Porphine](#)

18:20 to 18:40

**Susana Cordoba de Torresi** (Instituto de Quimica, Universidade de São Paulo, São Paulo, Brazil), Fabian A. Cerda Pastrian, Andreson Marques, Pedro H.C. Camargo

[Tuning the electrocatalytic properties of Cu<sub>2</sub>O nanoparticles by controlling size and geometry](#)

---

## Symposium 18: General Session

---

**Room : 101B**

*Chaired by:* Leigh Aldous and Yann Leroux

14:00 to 14:20

**Alexander Oleinick** (Departement de Chimie, CNRS-ENS-UPMC UMR 8640 PASTEUR, Paris, France), Oleksii Sliusarenko, Irina Svir, Christian Amatore

[Validating a Central Approximation in Theories of Regular and Random Electrochemical Electrode Arrays](#)

14:20 to 14:40

**Ana Fernández-la-Villa** (R&D, Micrux Technologies, Oviedo, Spain), Diego F. Pozo-Ayuso, Mario Castaño-Álvarez

[New Strategies to Manufacture Low-cost Thin-film MicroElectrode Arrays for Electroanalysis](#)

14:40 to 15:00

**Ying Wan** (School of Mechanical Engineering, Nanjing University of Science and Technology, Nanjing, China), Pengjuan Wang, Yan Su

[Surface-Initiated Enzymatic Polymerization Based Signal Amplification Strategies for Sensitivity Improvement of Electrochemical DNA Sensors](#)

15:00 to 15:20

**Conchi Ania** (INCAR, CSIC, Oviedo, Spain), Alicia Gomis-Berenguer, Naiara Hernández-Ibañez, Jesus Iniesta

[Conductive mesoporous carbon electrodes for biosensing applications](#)

15:20 to 15:40

**Maria Cuartero** (Department of Inorganic and Analytical Chemistry, University of Geneva, Geneva, Switzerland), Gaston Crespo, Eric Bakker

[Thin Layer Ionophore-Based Membranes Electrochemically modulated by Poly\(3-octylthiophene\) for Multianalyte Detection](#)

15:40 to 16:00

**Saimon Moraes Silva** (Chemistry, The University of New South Wales, Sydney, Australia), Roya Tavallaie, Muhammed Alam, J. Justin Gooding

[Electrochemical Characterization of Gold-Coated Magnetic Nanoparticles as 'Dispersible Electrodes'](#)

16:00 to 16:20

**Jen-Yuan Wang** (Physics Division, Institute of Nuclear Energy Research, Taoyuan, Taiwan), Tse-Chuan Chou, Lin-Chi Chen, Kuo-Chuan Ho

[Amperometric Detection of Hemoglobin A1c using a Poly\(3-aminophenylboronic acid\) Thin Film with Binding-Induced Ion Flux Blocking](#)

16:20 to 16:40 Coffee Break

16:40 to 17:00

**Alicia Gomis-Berenguer** (Procesos químicos en energía y medio ambiente, Instituto nacional del carbón (INCAR-CSIC), Oviedo, Spain), Verónica Celorrio, David J. Fermín, Jesus Iniesta, Conchi O. Ania

[A glance at the photoelectrochemical response of nanoporous carbon/semiconductor electrodes](#)

17:00 to 17:20

**Leigh Aldous** (School of Chemistry, The University of New South Wales, The University of New South Wales, Sydney, Australia), Wuan Xin Teh, Trang Quynh To, Sean Cadogan

[Ferrocenium triiodide ionic liquids: Synthesis, electron transfer and their \(thermo\)electrochemical waste heat harvesting properties](#)

17:20 to 17:40

**Dan Nguyen Dang** (UR ABTE - EA 4651 & CRISMAT UMR6508 CNRS, IUT de Caen, Univ. Caen Basse-Normandie, Caen, France), Stéphanie Gascoin, Cosmelina G. Da Silva, Richard Retoux, Benoît Riffault, Daniel Chateigner, Otavio Gil

[Volume Synthesis of Calcareous Deposit on Carbon Steel in Natural Seawater: Effect of Two-Step Applied Potential Waveform](#)

17:40 to 18:00

**Zhang Dalei** (College of Mechanical and Electronic Engineering, China University of Petroleum, Qingdao, China)

[Wire Beam Electrode Technique for Investigation Galvanic Corrosion Behavior between Zinc and Carbon Steel](#)

18:00 to 18:20

**Miikka Jokinen** (Department of Chemistry, Aalto University, Espoo, Finland), José A. Manzanares, Kyösti Kontturi, Lasse Murtoimäki

[Thermal membrane potential - Application to thermoelectric power generation](#)

Closing Ceremony 12:30 to 12:50 (Plenary Hall)											

# Friday, 9 October 2015 - Morning

---

## Plenary Lecture

**Room : Plenary Hall**

*Chaired by:* Justin Gooding

### 09:15 to 09:15 **Electrochimica Acta Gold Medal**

**Alan Bond** (Chemistry, Monash University, Clayton, Australia)

[A Voltammetric Odyssey: From Homogeneous Dropping Mercury to Heterogeneous Macro and Nano Electrodes: From the Manual Era to Advanced Automated High Speed Computation](#)

---

## Symposium 1: New Directions in Analytical Electrochemistry

**Room : 103**

*Chaired by:* Jyh-Myng Zen and Jie Zhang

09:30 to 09:50

**Gaston Crespo** (Inorganic and Analytical Chemistry, University of Geneva, Geneva, Switzerland), Majid Ghahraman Afshar, Eric Bakker

[Selective Proton Pump for Thin Layer Chemical Modulations](#)

09:50 to 10:10

**Daniel Mandler** (Institute of Chemistry, Hebrew University of Jerusalem, Jerusalem, Israel), Shlomit Kraus, Netta Bruchiel-Spanier, Yamit Pisman, Maria Hitrik

[Nanoparticles Imprinted Polymers \(NIP\): Speciation of Nanoparticles](#)

10:10 to 10:30

**Damien Arrigan** (NRI & Chemistry, Curtin University, Perth, Australia), Yang Liu, Masniza Sairi, Gregor Neusser, Christine Kranz

[Achieving diffusional independence in arrays of liquid-liquid nanointerfaces: improving the electroanalytical performance](#)

10:30 to 10:50

**Lin-Chi Chen** (Department of Bio-Industrial Mechatronics Engineering, National Taiwan University, Taipei, Taiwan), Chieh-Wen Yao, Chia-Hao Chang, Chih-Hao Chen, Che-Lun Chang, Hung-Yun Liao

[Stability-enhanced Screen-Printed Ion-Selective Electrodes \(SPISEs\) for Plant Factory and Smart Farming Applications](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30

**Zhang Meining** (Department of Chemistry, Renmin University of China, Beijing, China)

[Patterning of Microelectrode Array with soft lithography for Biological Sensing](#)

## Symposium 3: Batteries for Tomorrow's World

Room : 201AB

Chaired by: She-huang Wu

09:30 to 10:10 Keynote

**T. Richard Jow** (Energy and Power Division, U.S. Army Research Laboratory, Adelphi, USA), Jan Allen, Joshua Allen, Samuel Delp, Jeffrey Wolfenstine

[Challenges and Progress in Developing High Voltage Li-ion Batteries](#)

10:10 to 10:30

**Liwei Zhao** (Elements Strategy Initiative for Catalysts and Batteries, Kyoto University, Fukuoka, Japan), Shigeto Okada

[A comparison of the thermal stability of electrolytes for Li- and Na-ion batteries](#)

10:30 to 10:50

**Katsuhiko Tsunashima** (Department of Materials Science, National Institute of Technology, Wakayama College, Wakayama, Japan), Hayato Fujimoto, Hsien Hau Wang, Larry Curtiss, Khalil Amine, Youhei Mizuguchi

[Electrochemical Behavior of Oxygen in Phosphonium Ionic Liquids as Electrolytes for Lithium Air Batteries](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30 Invited

**W. Wieczorek** (Faculty of Chemistry, Warsaw University of Technology, Warsaw, Poland), M. Dranka, J. Zachara, Marek Marcinek, L. Niedzicki, M. Kalita, Anna Bitner-Michalska, G. P. Jankowski, Z. Zukowska

[Studies on ionic transport in liquid and polymeric electrolytes based on novel organic salts](#)

11:30 to 11:50

**K. Uta Schwenke** (Technical Electrochemistry, Technische Universität München, Garching bei München, Germany), Sophie Solchenbach, Benjamin Strehle, Michael Metzger, Stefano Meini, Julien Demeaux, Brett L. Lucht, Hubert A. Gasteiger

[The impact of CO<sub>2</sub> evolved from the reduction of VC and FEC during the formation cycle of lithium-ion batteries](#)

11:50 to 12:10

**Atetegeb Meazah Haregewoin** (Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan)

[Design of Sulfur Based Electrolyte Additives for Advanced Lithium-ion Batteries](#)

12:10 to 12:30

**Chao Xu** (Department of Chemistry-Angström Laboratory, Uppsala University, Uppsala, Sweden), Fredrik Lindgren, Bertrand Philippe, Mihaela Gorgoi, Fredrik Björefors, Kristina Edström, Torbjörn Gustafsson

[Improved Performance of Silicon Anode for Li-Ion Batteries: Understanding the Surface Modification Mechanism of Fluoroethylene Carbonate as an Effective Electrolyte Additive](#)

---

## Symposium 3: Batteries for Tomorrow's World

---

**Room : 201C**

*Chaired by:* Gao Liu

09:30 to 09:50

**Helmut Baltruschat** (Chemistry, University of Bonn, Bonn, Germany), Christoph Bondué

[Oxygen Reduction and Evolution for Li-Air batteries: Role of the Electrocatalyst](#)

09:50 to 10:10

**James T. Frith** (Chemistry, University of Southampton, Southampton, United Kingdom), Luyi Yang, Nuria Garcia-Araez, John R. Owen

[Homogeneous Catalysts for Li-Oxygen Cells](#)

10:10 to 10:30

**Guoqing Wang** (School of Materials Science and Engineering, Zhejiang University, Hangzhou, China), Shuangyu Liu, Jian Xie, Fangfang Tu, Shichao Zhang, Tiejun Zhu, Gaoshao Cao, Xinbing Zhao

[RuO<sub>2</sub>-nanoparticles-coated  \$\delta\$ -MnO<sub>2</sub> as efficient catalytic cathode for high-performance Li-O<sub>2</sub> batteries](#)

10:30 to 10:50

**Jing-Hua Tian** (School of Energy, Soochow University, Suzhou, China), Yujiao Xu, Yue Fu, Jin Wang, Ruizhi Yang

[Synthesis and Catalytic Activity of Ni Doped CoFe<sub>2</sub>O<sub>4</sub> Hollow Nanospheres as Bi-functional Catalysts for Lithium Air Batteries](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30

**Masaki Yamagata** (Faculty of Chemistry, Materials and Bioengineering, Kansai University, Suita, Japan), Yukiko Matsui, Takuya Takahashi, Satoshi Uchida, Masashi Ishikawa

[How to make an ideal electrolyte based on bis\(trifluorosulfonyl\)imide-based ionic liquid for lithium-ion and lithium-sulfur batteries](#)

11:30 to 11:50

**Fu-Ming Wang** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan)

[Self Terminated Oligomer Branched Architecture \(STOBA\) in lithium ion battery](#)

11:50 to 12:10

**Masahiro Shimizu** (Chemistry and Biotechnology, Tottori University, Tottori, Japan), Hiroyuki Usui, Hiroki Sakaguchi

[Application of ionic liquid electrolytes to Si electrode as a Li-ion battery anode](#)

12:10 to 12:30

**Seung Sik Hwang** (Energy Lab, Samsung Advanced Institute of Technology, Samsung Electronic, Suwon-si, Korea), Jun-Hwang Ku, Jae-Man Choi

[Lithium Containing Polymeric Binder for Improved Performance of Li-Ion Batteries](#)

## Symposium 4: Advances in Fuel Cells from Materials to Systems

Room : 102

Chaired by: Anne Hauch and Nguyen Minh

09:30 to 09:50 Invited

**Nguyen Minh** (Center for Energy Research, University of California, San Diego, La Jolla, USA)

[Solid Oxide Fuel Cells - A Clean and Efficient Energy Technology for the Future](#)

09:50 to 10:10

**Aziz Nechache** (Division of Physical Sciences and Engineering, King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia), Samir Boulfrad, Mark Cassidy, Enrico Traversa, John T.S. Irvine

[Study of LSCM-CGO-Ni Anode Characteristics by Electrochemical Impedance Spectroscopy](#)

10:10 to 10:30

**Anne Hauch** (Department of Energy Conversion and Storage, Technical University of Denmark, Roskilde, Denmark), Karen Brodersen, Peter Stanley Jørgensen, Ming Chen

[Ni/YSZ Electrodes Optimized for Stability at High Electrolysis Current Density](#)

10:30 to 10:50

**Sergey Rashkeev** (Theory, Modeling & Simulation, Qatar Environment & Energy Research Institute, Doha, Qatar), Michael Glazoff, Stephen Herring

[Towards Control of Major Degradation Processes in Solid Oxide Electrolysis Cells](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30

**Lucia Fernandez Macia** (Electrochemical and Surface Engineering group, Vrije Universiteit Brussel, Brussels, Belgium), Dries Van Laethem, Sigelinde Steenberge, Diederik Depla, Johan Deconinck, Annick Hubin

[Advanced EIS Study of the Ionic Conduction in Nanocrystalline Yttrium-Doped Ceria](#)

11:30 to 11:50

**Junfu Bu** (Department of Materials Science and Engineering, KTH Royal Institute of Technology, Stockholm, Sweden), Pär Jönsson, Zhe Zhao

[BaZr<sub>x</sub>Ce<sub>0.8-x</sub>Y<sub>0.2</sub>O<sub>3-δ</sub> \(x = 0.5, 0.6, 0.7\) Proton Conductors Prepared by Spark Plasma Sintering](#)

## Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication

Room : 101C

Chaired by: Nikolay Dimitrov and Andrew Gewirth

09:30 to 09:50 Invited

**Shuehlin Yau** (Chemistry, National Central University, Zhongli, Taiwan)

[In situ Scanning Tunneling Microscopy Imaging Self-Assembled Monolayers of Mercaptoacetic Acid and Cupric Ion on Au\(111\) Electrode](#)

09:50 to 10:10

**Andrew Lodge** (Department of Chemistry, University of Southampton, Southampton, United Kingdom), Calum Robertson, Andrew Hector

[The Synthesis and Characterisation of Mesoporous Silica Films for use in Supercritical Fluid Electrodeposition](#)

10:10 to 10:30

**W. Schwarzacher** (Physics, University of Bristol, Bristol, United Kingdom), R. J. Brooke, Chengjun Jin, D. S. Szumski, R. J. Nichols, Bingwei Mao, K. S. Thygesen

[A Ni - 4,4'-bipyridine - Ni single-molecule electrochemical transistor](#)

10:30 to 10:50

**Marco Musiani** (IENI, CNR, Padova, Italy), Sandro Cattarin, Nicola Comisso, Paolo Guerriero, Luca Mattarozzi, Enrico Verlato

[Oxygen Bubble Templated Anodic Deposition of Porous PbO<sub>2</sub>](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30

**Damian Kowalski** (Laboratoire de Recherche en Nanosciences, University of Reims Champagne-Ardenne, Reims, France)

[TiO<sub>2</sub> Nanotubes with Wide Spacing – a Platform for Electrodeposited Nanostructures](#)

11:30 to 11:50

**Jianming Li** (Research Institute of Petroleum Exploration & De, PetroChina, Beijing, China), Jin Xu, Xiaoqi Wang, Liang Sun, Songtao Wu

[Characterization of the microstructure of reservoirs using electrodeposition method](#)

11:50 to 12:10

**Honorata Kazimierzak** (Institute of Metallurgy and Materials Science, Polish Academy of Sciences, Krakow, Poland), Agnieszka Hara, Piotr Ozga

[Electrodeposition of Zn-Mn-Mo layers from citrate solutions](#)

12:10 to 12:30

**Derck Schlettwein** (Institute of Applied Physics, Justus-Liebig-University Giessen, Giessen, Germany), Martina Stumpp, Thi Hai Quyen Nguyen, Christian Lupo

[Interplay of Different Reaction Pathways in the Pulsed Galvanostatic Deposition of ZnO](#)

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 101A**

*Chaired by:* Lindsay Wilson and Dejin Zang

09:30 to 09:50

**Chuan Zhao** (School of Chemistry, The University of New South Wales, Sydney, Australia), Xunyu Lu, Changlong Xiao

[Three Dimensional Precious Metal Free Electrocatalysts for Water Splitting](#)

09:50 to 10:10

**Dejin Zang** (Chemistry, University of Strasbourg, Institute of Chemistry, Strasbourg, France), Antoine Bonnefont, Laurent Ruhlmann

[Porphyrin-Polyoxometalates@Pt Modified Electrodes for Electrocatalytic Hydrogen Evolution Reaction](#)

10:10 to 10:30

**Wei-Fu Chen** (Chemistry Department, Brookhaven National Laboratory, Upton, USA), Kotaro Sasaki, Jonathan Schneider, Chiu-Hui Wang, James Muckerman, Etsuko Fujita

[Nitride-Stabilized Tungsten Carbide Electrocatalysts for Hydrogen Evolution Reaction](#)

10:30 to 10:50

**Zhaoxiong Xie** (Department of Chemistry, Xiamen University, Xiamen, China), Qiaoli Chen, Haixin Lin, Yanyan Jia, Zhenming Cao, Yaqi Jiang, Lansun Zheng

[Supersaturation Dependent Evolution of Nanocrystal Surfaces and its Application in the Synthesis of Noble Metal Nanocatalysts with Enhanced Electrocatalytic Properties](#)

10:50 to 11:10 Coffee Break

11:10 to 11:30

**Lindsay Wilson** (Chemistry, University of the Western Cape, Cape Town, South Africa), Candice Rassie, Priscilla Baker, Emmanuel Iwuoha

[Electrochemical Responses of Transglutaminase Immunosensor Developed on a Polypyrrole-Cobalt \(II\) Salicyladiimine Dendritic Composite Material](#)

11:30 to 11:50

**Erika Bustos** (Science, Centro de Investigación y Desarrollo Tecnológico en Electroq, Querétaro, Mexico), Rosa Herrada, Oswaldo Cuevas, Federico Manríquez, Alejandro Medel, Igancio Sirés

[Electrocatalytic Effect of IrO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub>/Ti in the Electrochemical Degradation of Phenanthrene, Naphthalene and Fluoranthene in Wastewater from the Electrokinetic Treatment of Polluted Soil by Hydrocarbons](#)

11:50 to 12:10

**Xue Leng** (School of Chemistry and Molecular Biosciences, the University of Queensland, Brisbane, Australia)

[Reduction Induced Surface Amorphization Enhances Oxygen Evolution Reaction Activity in Co<sub>3</sub>O<sub>4</sub>](#)

12:10 to 12:30

**Chen-Hao Wang** (Department of Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Vuri Ayu Setyowati, Hsin-Chih Huang

[Effect of Iron Precursor on Oxygen Reduction Reaction of Fe-N-C Catalyst in PEMFC](#)

---

## Symposium 9: Electrocatalytic Materials

---

**Room : 201EF**

*Chaired by:* Christian Engelbrekt and Petr Krtil

09:30 to 09:50

**Chia-Ying Chiang** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Po-Tso Ting

[Multi-Components Amorphous Metal-Oxides Catalysts for Oxygen Evolution Reaction](#)

09:50 to 10:10

**Cheng-Lan Lin** (Department of Chemical and Materials Engineering, Tamkang University, New Taipei City, Taiwan), Ju-Yu Yeh

[Preparation and Characterization of Platinum Nanoparticles Supported on Silica-Carbon Black Nanocomposites for Methanol Oxidation Reaction](#)

10:10 to 10:30

**Petr Krtil** (Electrocatalysis, J. Heyrovsky Institute of Physical Chemistry, Prague, Czech Republic), Tatsuya Hiratoko, Hana Hoffmannova, Jonathan Mueller, Timo Jacob

[Dynamics of Pt/Ru Based Alloy Catalysts in Formate Oxidation Process – a DFT and In-Situ XAS Approach](#)

10:30 to 10:50

**Daniel Guay** (Énergie, Matériaux, Télécommunications, INRS, Varennes, Canada), Claudie Roy, Sébastien Garbarino, Ifan Stephens, Ib Chorkendorff

[Electroreduction of CO on mesoporous Cu and oxide-derived mesoporous Cu electrodes](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30

**Wen-Bin Cai** (Department of Chemistry, Fudan University, Shanghai, China), Kun Jiang, Ye Wang

[Bridging across Electrocatalytic Performances of Nanomaterials & Interfacial Species Evolution with Realtime ATR-IR Spectroscopy](#)

11:30 to 11:50

**Christian Engelbrekt** (Department of Chemistry, Technical University of Denmark, Lyngby, Denmark),  
Nedjeljko Seselj, Jens Ulstrup, Jingdong Zhang

[Facile synthesis of starch-scaffolded bimetallic Au-Pt nanostructure and electrocatalysis](#)

11:50 to 12:10

**Kobra Ghobadi** (Chemistry, Yazd University, Yazd, Iran (Islamic Republic of)), Hamid Reza Zare, Hossein Khoshro, Alireza Gorji, Abbas Ali Jafari

[A Study of the Catalytic Activity of a Schiff Base Ligand on Electrochemical Reduction of Carbon Dioxide: Indirect Electrocatalytic Synthesis of Isonicotinic Acid](#)

---

## Symposium 11: New Important Frontiers in Molecular Electrochemistry

---

**Room : 201D**

*Chaired by:* Olivier Buriez, Kazuhiro Chiba, Flavio Mara and Jean-Michel Saveant

09:30 to 09:50

**Wenjing Hong** (Department of Chemistry and Biochemistry, University of Bern, Bern, Switzerland), Masoud Baghernejad, Cancan Huang, Thomas Wandlowski

[Break Junction under Electrochemical Gating: Fermi-level Tuning and Redox Manipulation](#)

09:50 to 10:10

**Toshio Fuchigami** (Department of Electronic Chemistry, Tokyo Institute of Technology, Yokohama, Japan), Shinsuke Inagi

[Selective Electrochemical Fluorination of Organic Molecules and Macromolecules Using Poly\(HF\) Salt Ionic Liquids](#)

10:10 to 10:50 Keynote

**Jean-Michel Saveant** (Chemistry, Université Paris Diderot (Paris 7), Paris 13, France)

[Current Issues in Molecular Catalysis Illustrated by Iron Porphyrins as Catalysts of the CO<sub>2</sub>-to-CO Electrochemical Conversion](#)

10:50 to 11:10 Coffee Break

11:10 to 11:30

**Joanne Tory** (Chemistry, University of Reading, Reading, United Kingdom), František Hartl

[Transition Metal  \$\alpha\$ -Diimine Carbonyl Complexes for Electrocatalytic CO<sub>2</sub> Reduction](#)

11:30 to 11:50

**Xinsheng Zhang** (Department of Chemical Reaction Engineering, East China University of Science and Technology, Shanghai, China), Ling Jin, Dongfang Niu

[Action Mechanism of Quaternary Ammonium Compound in the Electroreduction of Oxalic Acid to Glyoxylic Acid](#)

11:50 to 12:10

**Hiroyuki Ueda** (Graduate School of Science and Technology, Kumamoto University, Kumamoto, Japan), Katsuhiko Nishiyama, Soichiro Yoshimoto

[Influence of Cations on the Control of the Multiple Redox States of Fullerene at the Ionic Liquid Electrochemical Interface](#)

## Symposium 14: Modeling, Design and Characterization of Nanostructured, Electroactive and Multifunctional Materials

**Room : 101D**

*Chaired by:* Masa-aki Haga and Alessandro Minguzzi

09:30 to 09:50 Invited

**Enrico Verlato** (IENI-CNR, CNR, Padova, Italy), Simona Barison, Wenyan He, Didier Floner, Florence Fourcade, Abdeltif Amrane, Florence Geneste, Marco Musiani

[Deposition of Ag Nanostructures on Ni-based 3D Electrodes and their Application as Electrocatalysts](#)

09:50 to 10:10

**Guobao Xu** (State Key Laboratory of Electroanalytical Chemistry, Changchun Institute of Applied Chemistry, Chinese Academy of, Changchun, China), Jianping Lai, Wenxin Niu, Ling Zhang

[Shape-Controlled and Size-Controlled Synthesis of Metal Nanocrystals and Their Electrochemical Applications](#)

10:10 to 10:30

**Kenta Imai** (Department of Chemistry, University of Bologna, Bologna, Italy), Giovanni Valenti, Elena Villani, Massimo Marcaccio, Luca Prodi, Francesco Paolucci

[Effect of Electrode Surface-State Change on Electrogenenerated Chemiluminescence from a Ruthenium-Doped Silica Nanoparticle](#)

10:30 to 10:50

**Joanna Dolinska** (Department of Electrode Processes, Institute of Physical Chemistry Polish Academy of Sciences, Warsaw, Poland), Arunraj Chidambaram, Zahra Taleat, Witold Adamkiewicz, Wojciech Lisowski, Michalina Iwan, Barbara Palys, Volodymyr Sashuk, Tomasz Andryszewski, Marcin Opallo, Liza Rassaei

[Electrocatalytic Oxidation of Biologically Active Compoundson MoS<sub>2</sub> Nanopetal Stacks Decorated with Carbon or Gold Nanoparticles](#)

10:50 to 11:10

Coffee Break

11:10 to 11:50 Keynote

**Gyeong S. Hwang** (McKetta Department of Chemical Engineering, University of Texas at Austin, Austin, USA)

[Understanding and Predicting the Photocatalytic Properties of Bismuth Vanadate from First Principles](#)

11:50 to 12:10

**Herenilton Oliveira** (Chemistry, Universidade de São Paulo, Ribeirão Preto, Brazil), Jane Machado

[Preparation, Characterization, and Electrochemical Properties of Monolith Glass-like Carbon-Silica Composites](#)

---

## Symposium 18: General Session

---

**Room : 101B**

*Chaired by:* Micheal Scanlon and Neeraj Sharma

09:30 to 10:10 Keynote

**Aicheng Chen** (Department of Chemistry, Lakehead University, Thunder Bay, Canada)

[Palladium-Based Nanomaterials: Synthesis and Electrochemical Applications](#)

10:10 to 10:30

**Andrei Ionut Mardare** (Institut for Chemical Technology of Inorganic Materials, Johannes Kepler University Linz, Linz, Austria), Christian Siket, Cezarina Cela Mardare, Siegfried Bauer, Achim Walter Hassel

[Dynamics of Interfacial Oxide Formation during Anodization of Valve Metal Superimposed Ultra-Thin Films](#)

10:30 to 10:50

**Micheal Scanlon** (Department of Chemistry & Tyndall National Institute, University College Cork, Cork, Ireland), Andres Molina Osorio

[Functionalization of Conductive Carbon Supports at Water/Oil Interfaces with Non-Precious Metal Hydrogen Evolution Catalysts](#)

10:50 to 11:10

Coffee Break

11:10 to 11:30

**Sung-Wook Kim** (Nuclear Fuel Cycle Process Development Group, Korea Atomic Energy Research Institute, Daejeon, Korea), Eun-Young Choi, Wooshin Park, Hun Suk Im, Jin-Mok Hur

[Conductive Ceramics as O<sub>2</sub>-Evolving Anodes for Electrolytic Reduction of Metal Oxides](#)

# Poster presentation program

## Symposium 1: New Directions in Analytical Electrochemistry

### Analytes

s01-001

**Shu-Hua Cheng** (Department of Applied Chemistry, National Chi Nan University, Nantou Hsien, Taiwan), Yen-Hua Liao, Ya-Ling Su

[Electrochemical Determination of Bisphenol A at Conducting Poly\(diallyldimethylammonium chloride\) Film-Modified Preanodized Screen-Printed Carbon Electrodes](#)

s01-002

**Xiaorong Gan** (School of Environmental Science and Technology, Dalian University of Technology, Dalian, China)

Highly Sensitive Electrochemical Sensor for Cu (II) Ions Based on Three-dimensional Porous  $H_xTiS_2$  Nanosheet-polyaniline

s01-003

**Huangxian Ju** (State Key Laboratory of Analytical Chemistry for Life Science, Nanjing University, Nanjing, China)

Amplified Electrochemical Analysis of DNA and Proteins

s01-004

**Akira Kotani** (School of Pharmacy, Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan), Mizuki Watanabe, Kazuhiro Yamamoto, Fumiyo Kusu, Hideki Hakamata

High-performance Liquid Chromatography with Electrochemical Detection for Determining a Ratio of Eicosapentaenoic Acid to Arachidonic Acid in Human Plasma

s01-005

**Si-Ping Wang** (Chang Gung University, Taoyuan, Taiwan), Trav Huang, Andrew S. Lin

Study of the Electrochemical Oxidation of Dissolved Carbon Monoxide in Acidic and Alkaline Electrolytes by Using and Fabricated Au-Microelectrode

### Data analysis

s01-006

**RyeoYun Hwang** (Graduate School of Analytical Science & Technology, Chungnam National University, Daejeon, Korea), Oc Hee Han, Young-Seok Byun

Multiple On-line NMR System Development to Detect Electrochemical Reactions of Direct Alcohol Fuel Cells

s01-007

**Jan Vacek** (Department of Medical Chemistry and Biochemistry, Palacky University, Olomouc, Czech Republic), Jan Hrbac, Vladimir Halouzka, Libuse Trnkova

eL-Chem Viewer: A Freeware Package for the Analysis of Electrochemical Data

### Electrodes

s01-008

**Fethi Bedioui** (CNRS UTCBS 8258-Chimie ParisTech, Chimie ParisTech, Paris, France), Amandine Calmet, Sophie Griveau, Virginie Lair, Michel Cassir, Abdelilah Amar, Eliane Sutter, Philippe Brunswick

Corrosion behavior of biocompatible stainless steels in physiological medium for application to non-invasive diagnosis of small fiber neuropathies

s01-009

**Jan Clausmeyer** (Analytische Chemie, Center for Electrochemical Sciences, Ruhr-Universität Bochum, Bochum, Germany), Justus Masa, Edgar Ventosa, Wolfgang Schuhmann

Investigation of Single Ni(OH)<sub>2</sub> Nanoparticles: Electrocatalysis and Energy Storage at Ultrafast Mass Transport

s01-010

**Yingchun Li** (Pharmacy, School of Pharmacy, Shihezi University, Shihezi, China), Jie Liu, Han Song, Jiang Liu, Lu Zhang

Ultrasensitive electrochemical sensing of metronidazole using molecularly imprinted polymer decorated hollow nickel nanospheres on carbon nanotubes

s01-011

**Huei-Ping Liou** (Chemical and Materials Engineering, Chang Gung University, Tao-Yuan, Taiwan), Chia-Liang Sun

Microwave-Assisted Synthesis of Graphene Oxide Nanoribbons Using Green Chemistry for the Electrochemical Detection

s01-012

**Yanyan Song** (Research Center for Analytical Sciences, College of Sciences, Northeastern University, Yanyan Song, China), Tongtong Li

Cocoon Silk-Derived Carbon Nanospheres: Highly Activated Metal-Free Electrocatalysts for Reduction of Dissolved Oxygen and Glucose Sensing

s01-013

**Chia-Liang Sun** (Dept. of Chem. and Mater. Eng., Chang Gung University, Tao-Yuan, Taiwan), Chun-Hao Su, Jhing-Jhou Wu, Chen-Fu Pan

Synthesis of Short or Holey Graphene Oxide Nanoribbons for the Electrochemical Detection of Biomarkers

s01-014

**Takami Tsukuma** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Masatsugu Morimitsu

A Novel Electrochemical Sensing of Hydrogen Phosphate Ion with RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> Mixed Oxide

s01-015

**Giovanni Valenti** (Chemistry G. Ciamician, University of Bologna, Bologna, Italy), Martina Zangheri, Sandra Sansaloni, Mara Mirasoli, Alain Penicaud, Aldo Roda, Francesco Paolucci

Transparent Carbon Nanotube Network for Efficient Electrochemiluminescence Device

s01-016

**Guor-Tzo Wei** (Chemistry and Biochemistry, National Chung Cheng University, Chiayi, Taiwan)

The Modification of Screen-printed Carbon Electrodes with Polymerized Ionic Liquid Composites for Chemical Analysis

s01-017

**Yavuz Yardým** (Analytical Chemistry, Yüzüncü Yıl University, Faculty of Pharmacy, Van, Turkey), Metin Celebi, Abdulkadir Levent, Zühre Sentürk, Aydin Yigit

Using Graphene-Nafion Composite Film Modified Glassy Carbon Electrode for the Simultaneous Determination of Paracetamol, Aspirin and Caffeine in Pharmaceutical Formulations

s01-018

**Mingzhong Zou** (Condensed Matter Physics, Fujian Normal University, Fuzhou, China), Wenyu Yang, Xiang Chen, Guiying Zhao, Jiaxin Li, Yingbin Lin, Zhigao Huang

Suppression of degradation of lithium ion batteries for LiFePO<sub>4</sub>@C batteries by nano Si surface modification

## Techniques

s01-019

**Gan-Zuei Chang** (Department of Chemistry, University of Oxford, Oxford, United Kingdom), Robert Jacobs, Kylie Vincent

*In situ* ATR-IR spectroelectrochemical study of the deactivation of Pd/C catalysts used in DFAFC by common impurities found in formic acid

s01-020

**Guy Denuault** (Chemistry, University of Southampton, Southampton, United Kingdom), Ana Cristina Perdomo Marin

An *in-situ* Microelectrode Study of the Sea Surface Microlayer: Experimental and Theoretical Challenges

s01-021

**Ertugrul Keskin** (Analytical Chemistry, Adiyaman University, Faculty of Pharmacy, Adiyaman, Turkey), Yavuz Yardim, Abdulkadir Levent, Zuhre Senturk

Electrochemical determination of Norepinephrine by adsorptive stripping voltammetry using a boron doped diamond electrode

s01-022

**Genxi Li** (Department of Biochemistry, Nanjing University, Nanjing, China), Hao Li, Yue Huang, Luming Wei, Weiwei Li, Xiaoli Zhu

Fabrication of Electrochemical Biosensor by Using Peptide as a New Kind of Recognition Element

s01-023

**Samuel Perry** (Chemistry, University of Southampton, Southampton, United Kingdom), Guy Denuault

Normalised Sampled-Current Voltammetry at Microdisc Electrodes: Kinetic Information from Pseudo Steady State to Steady State Voltammetry

s01-024

**Yukihiro Shintani** (School of Science and Engineering, Tokyo, Japan)

Characterization of Polycrystalline Doped-diamond Electrolyte-solution-gate Field-effect Transistor pH Sensor with/without Termination Control

s01-025

**Simon Theil** (ZSW - Ulm, Zentrum für Sonnenenergie und Wasserstoffforschung, Ulm, Germany), Margret Wohlfahrt-Mehrens

Investigation of cell aging by analysis of electrolyte decomposition *via* gas chromatography

s01-026

**Her Shuang Toh** (Department of Chemistry, Oxford University, Oxford, United Kingdom), Richard Compton

'Nano-impacts': An Electrochemical Technique for Nanoparticle Sizing in Optically Opaque Solutions

s01-027

**Yavuz Yardým** (Analytical Chemistry, Yüzüncü Yıl University, Faculty of Pharmacy, Van, Turkey)

Square-Wave Adsorptive Stripping Voltammetric Determination of Resveratrol Using Boron-Doped Diamond Electrode in the Presence of Hexadecyl Trimethyl Ammonium Bromide

s01-028

**Chuan Zhao** (School of Chemistry, The University of New South Wales, Sydney, Australia), Asim Khan

Oxygen Reduction Reactions in Ionic Liquids-Based Mixture Electrolytes for High Performance Rechargeable Li-O<sub>2</sub> Batteries

s01-029

**Javier Izquierdo Pérez** (Institute of Analytical and Bioanalytical Chemistry, University of Ulm, Ulm, Germany), B. Mizaikoff, C. Kranz

[An Analytical Platform for the Characterization of Electrochemical Processes at AuNPs-Modified BDD Electrodes](#)

s01-030

**Omotayo Arotiba** (Applied Chemistry, University of Johannesburg, Johannesburg, South Africa) Olayiwola Idris, Nonhlangabezo Mabuba

[Dealing with Interferences in the Electrochemical Detection of Arsenic – a Complexometric Masking Approach](#)

## Symposium 2: Electrochemical Aspects of Biological Systems: Theory, Experiment and Applications

### Bio-device

s02-001

**Stefania Rapino** (Chemistry Department G. Ciamician, University of Bologna, Bologna, Italy), Mirella Trinei, Matteo Iurlo, Eleonora Ussano, Alice Soldà, Giovanni Valenti, Pier-Giuseppe Pelicci, Francesco Paolucci, Massimo Marcaccio, Marco Giorgio

Development of an Electrochemically Based Rapid, Low-cost and Spreadable Assay for Heart Injury and Cancer Related Pathologies

s02-002

**Mistuo Sano** (Precision and Intelligence Laboratory, Tokyo Institute of Technology, Yokohama, Japan), Yuma Tahara, Chun-Yi Chen, Tomoko Hashimoto, Hiromichi Kurosu, Masato Sone

Pd Catalyzation and Electroless Deposition of Ni on Textile Using Supercritical Carbon Dioxide

### Biochip

s02-003

**Ausra Baradoke** (Department of Nanoengineering, Center for Physical Sciences and Technology, Vilnius, Lithuania), Aneta Radzevic, Raimonda Celiesiute, Ramunas Valiokas, Rasa Pauliukaite

Graphene Electrodes for Electrochemical Detection of Biomarkers

### Bioelectrocatalysis

s02-004

**Sofiene Abdellaoui** (Chemistry, University of Utah, Salt Lake City, USA)

New enzymes for the hybrid enzymatic and organic electrocatalytic cascade for the complete oxidation of glycerol

s02-005

**Fred Lisdat** (Biosystems Technology, Institute of Applied Life Sciences, Technical University Wildau, Wildau, Germany), J. Gladisch, D. Sarauli, B. Schulz

Electrospun, conductive polymer fleeces as electrode materials for enhanced bioelectrocatalysis

### Biofuel

s02-006

**Adalgisa De Andrade** (Chemistry, FFCLRP/USP, Universidade de São Paulo, Ribeirao Preto, Brazil), Sidney Aquino-Neto, Ana L. R. L. Zimbardi, Franciane P. Cardoso, Lais B. Crepaldi, Rosa R.P.M. Furriel

Biocathodes Using a Laccase from *Pycnoporus sanguineus* and their Potential Application in Methanol/O<sub>2</sub> Biofuel Cell

s02-007

**Isao Shitanda** (Department of Pure and Applied Chemistry, Tokyo University of Science, Chiba, Japan), Saki Nohara, Seiya Tsujimura, Yoshinao Hoshi, Masayuki Itagaki

Fabrication of Paper-based Disk-shaped Glucose Biofuel Array

### Biointerface

s02-008

**Eun Joong Kim** (Department of Chemistry, Seoul National University, Seoul, Korea), Taek Dong Chung

Fabrication of Artificial Synaptic Interfaces Using Engineered Synaptic Adhesion Proteins

s02-009

**Alexander Vaskevich** (Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel), Tatyana B. Bendikov, Ortal Bachar, Frolov Ludmila, Israel Rubinstein

Effect of Nanoscale Surface Morphology on Biorecognition Using Localized Surface Plasmon Resonance (LSPR) Spectroscopy

**Biosensor**

s02-010

**Jingyi Chen** (College of Chemistry and Chemical Engineering, Jiangxi Normal University, Nanchang, China)  
An Ultrasensitive pH-Switchable Electrochemical Immunosensing based on Integrated 3D-KSCs Electrode as Singal Collector and AuNPs-Ab<sub>2</sub>-GOD-ConA as Tracing Tag for Assay of CEA

s02-011

**Shengyuan Deng** (School of Environmental and Biological Engineering, Nanjing University of Science and Technology, Nanjing, China)  
Label-Free Biomimetic Electrocatalysis-Induced Precipitation for Ultrasensitive Bioanalysis

s02-012

**Juan He** (College of Chemistry and Chemical Engineering, Jiangxi Normal University, Nanchang, China), Li Wang  
The GOD/Cu-Hemin Metal Organic Frameworks Nanocomposites for Glucose Sensing

s02-013

**Bang-De Hong** (Department of Chemical and Materials Engineering, National Kaohsiung University of Applied Sciences, Kaohsiung City, Taiwan), Chien-Liang Lee  
Defective graphene flake-supported Pd nanocubes as electrochemical glucose sensor

s02-014

**Shih-Han Huang** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan), Fu-Ming Wang  
Ultra-sensitive electrochemical electrode developed for ovarian cancer

s02-015

**Yuki Igaki** (Graduate School of Material Science, University of Hyogo, Ako, Japan), Fumio Mizutani, Tomoyuki Yasukawa  
Measurement of oxygen consumption of contracting C<sub>2</sub>C<sub>12</sub> myotube using scanning electrochemical microscopy

s02-016

**Bohdan Josypcuk** (Biomimetic Electrochemistry, J. Heyrovsky Institute of Physical Chemistry, Prague, Czech Republic), Oksana Josypcuk  
Biosensors with Electrochemical Detection at High Negative Potentials in Flow Systems

s02-017

**Yingchun Li** (Pharmacy, School of Pharmacy, Shihezi University, Shihezi, China), Han Song, Jie Liu, Lu Zhang, Jiang Liu, Yuan Liu  
Ultrasensitive and selective electrochemical sensor for dopamine determination based on novel supportless nanoporous Au-Ag alloy microrod

s02-018

**Ya-Yi Liang** (Department of Chemical and Materials Engineering, National Chin-Yi University of Technology, Taichung, Taiwan), Yung-Chien Luo, Jing-Shan Do  
Preparation and characterization of amperometric monoenzyme creatinine biosensor based on creatinine deiminase/PANI-PSSMA/Au/Al<sub>2</sub>O<sub>3</sub> electrode

s02-019

**Ming Jie Lin** (Department of Bio-industrial Mechatronics Engineering, National Chung Hsing University, Taichung, Taiwan), Ching Chou Wu  
Effect of the ratio of poly-L-lysine/glucose oxidase/ferricyanide composite on the sensing properties of second generation blood glucose sensors

s02-020

**Yang Liu** (Department of Chemistry, Tsinghua University, Beijing, China)  
Electrodeposited NiCo bimetallic nanoparticles decorated reduced graphene oxide for highly sensitive and selective determination of dopamine

s02-021

**Aimi Suzuki** (Materials Science, Faculty of Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan), Kazuki Murata, Seiya Tsujimura  
Characterization of Glucose Oxidase-Redox Hydrogel on MgO-templated Carbon Electrode

s02-022

**Junko Tanaka** (Research & Development Group, Hitachi, Ltd., Tokyo, Japan), Yu Ishige, Masao Kamahori  
Direct detection for ratio of concentrations of HbA1c to total hemoglobin with potentiometric immunoassay

s02-023

**Nozomu Tsuruoka** (Division of Material Science, Pure and Applied Sciences, University of Tsukuba, Tsukuba, Japan), Kazuki Murata, Seiya Tsujimura  
Glucose Biosensor based on a Glassy Carbon Electrode Modified with Poly(methylene green) and FAD-dependent Glucose Dehydrogenase

s02-024

**Shih-Han Wang** (Department of Chemical Engineering, I-Shou University, Kaohsiung City, Taiwan), Yi-Han Yen, Jing-Hwei Wang, Ming-Der Ger  
Improvement of Electrochemical Biosensor Performance for Hydrogen Peroxide Sensing Based on Iridium Nanoparticles Modified Graphene Oxide

s02-025

**Mikito Yasuzawa** (Department of Chemical Science and Technology, Tokushima University, Tokushima, Japan), Jiang Li, Masahiro Uchimar, Shunsuke Isoai, Yusuke Fuchiwaki  
Fabrication of Low Invasive Glucose Sensor for Continuous Glucose Monitoring

s02-026

**Yongchun Zhu** (Chemistry, Institute of Energy and Environment Catalysis, Shenyang Normal University, Shenyang, China), Jie Hao, Jianqiao Lang, Nan Xiao, Amin Bao  
Amperometric bromide biosensor based on graphite powder composite electrode modified with leaf paste of natural amaranth induced by spaying KBr aqueous solution

## Electron transfer

s02-027

**Xiao-Yuan Liu** (Department of Chemistry, East China University of Science and Technology, Shanghai, China)  
Electrochemistry-controlled Photo-induced Electron Transfer in Ubiquinone-based Systems

s02-028

**Galina Pankratova** (Department of Biochemistry and Structural Biology, Lund University, Lund, Sweden), Kamrul Hasan, Donal Leech, Lars Hederstedt, Lo Gorton  
Electrochemical Study of the Extracellular Electron Transfer of *Enterococcus faecalis* to Electrodes

s02-029

**Rasa Pauliukaite** (Department of Nanoengineering, Center for Physical Sciences and Technology, Vilnius, Lithuania), Raimonda Celiesiute, Aneta Radzevic, Tomas Rakickas, Zivile Ruzele, Sarunas Vaitekonis, Tautvydas Venckus  
Application of Polyfolates to the Development of Enzymatic Biosensors

## Membrane

s02-030

**Osamu Shirai** (Graduate School of Agriculture, Kyoto University, Kyoto, Japan), Yoshinari Takano, Yuki Kitazumi, Kenji Kano  
Propagation of the change in the membrane potential -Electrochemical elucidation on nerve conduction-

## Nanobiotechnology

s02-031

**Ewelina Zabost** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Wioletta Liwińska, Agnieszka Kowalczyk, Zbigniew Stojek  
Multicomponent hydrogel/aptamer-based nanofibers and nanoparticles for storing and release of intercalators and genetic material

**Nucleic acid**

s02-032

**Wioletta Liwińska** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Ewelina Zabost, Zbigniew Stojek

Nanoparticles designed from hydrogels and DNA in triple hybridisation process for improved storing and release of intercalators

**Protein**

s02-033

**Shengyuan Deng** (School of Environmental and Biological Engineering, Nanjing University of Science and Technology, Nanjing, China), Xubo Ji, Peng Xin, Dan Shan

An Electrogenerated Chemiluminescence Approach for the Assay of Zinc Finger Proteins (EGR1)

s02-034

**Sin-Cih Sun** (Department of Chemistry, Tunghai University, Taichung, Taiwan), Yuan-Hao Hsu, Min-Chieh Chuang

Interaction between Ferric/Ferrous Cytochrome c and Cardiolipin: An Electrochemical and Quartz Crystal Microbalance with Dissipation Study

**Techniques**

s02-035

**Christian Andre Gunawan** (School of Chemistry, The University of New South Wales, Sydney, Australia), Ekaterina Nam, Pall Thordarson, Chuan Zhao

Scanning Electrochemical Microscopy of Switchable Redox Enzyme Cascades

---

**Symposium 3: Batteries for Tomorrow's World**

---

**Li-ion and beyond li-ion battery systems**

s03-001

**Iain Aldous** (Stephenson Institute for Renewable Energy, University of Liverpool, Liverpool, United Kingdom), Laurence Hardwick

Adventures in Dioxygen Electrochemistry

s03-002

**Hajime Arai** (Kyoto University, Gokasho, Uji, Japan), Akiyoshi Nakata, Masaki Ono, Tadashi Kakeya, Tomokazu Yamane, Katsutoshi Fukuda, Hajime Tanida, Miwa Murakami, Yoshiharu Uchimoto, Zempachi Ogumi

Rechargeability of Zinc Electrodes Evaluated by *In Situ* Analysis

s03-003

**Arenst Andreas Arie** (Chemical Engineering, Parahyangan Catholic University, Bandung, Indonesia), Inez Devina, Ratna Frida Susanti, Hary Devianto, Martin Halim, Joong Kee Lee

Preparation and Electrochemical Performance of Turpentine Oil Derived Carbon Nanohorns as Anode Materials for Lithium-Ion Batteries

s03-004

**Arenst Andreas Arie** (Chemical Engineering, Parahyangan Catholic University, Bandung, Indonesia), Susan Olivia Limarta, Hans Kristianto, Martin Halim, Joong Kee Lee

Rice Husks Based Nanosilica as Anode Materials for Lithium-Ion Batteries

s03-005

**Chika Baba** (Dept of Sci of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Kenji Kawaguchi, Masatsugu Morimitsu

A High Energy Density of MH/Air Secondary Battery Using A<sub>2</sub>B<sub>7</sub> Type of Hydrogen Storage Alloys

s03-006

**Kolja Beltrop** (MEET Battery Research Center, WWU, University of Münster, Münster, Germany), Paul Meister, Olga Fromm, Martin Winter, Tobias Placke

Electrochemical Intercalation of Anions into Graphite – The Role of Anion Structure and Solvent Properties

s03-007

**Andrea Boschini** (Applied Physics, Chalmers University of Technology, Gothenburg, Sweden), Patrik Johansson  
Characterization of Sodium Based Ternary Polymer Electrolytes

s03-008

**Daniel Brandell** (Department of Chemistry, Uppsala University, Uppsala, Sweden), Bing Sun, Jonas Mindemark  
A Renaissance for Solid Polymer Electrolyte through Alternative Host Materials: Polycarbonates

s03-009

**Solveig Böhme** (Chemistry, Ångström Uppsala University, Uppsala, Sweden), Kristina Edström, Leif Nyholm  
Electrochemical behaviour of tin(IV) oxide electrodes in lithium-ion batteries at high potentials

s03-010

**Fei-Fei Cao** (College of Sciences, Huazhong Agricultural University, Wuhan, China)  
Facile Synthesis of CuO Nanochains as Anode Materials for Lithium-Ion Batteries

s03-011

**Suman Chae** (Materials Science and Engineering, Kunsan National University, Kunsan, Korea), Joongpyo Shim, Gyungse Park, Ho-Jung Sun

The Effects of Substrates on the Phase Formation Behavior and the Electrochemical Properties of  $\text{Li}_2\text{MnSiO}_4$  Cathode Thin Films Deposited by RF Sputtering for Thin Film Batteries

s03-012

**Chia-Chin Chang** (Department of Greenery Technology, National University of Tainan, Tainan, Taiwan), Li-Chia Chen, Yung-Der Juang

Effect of nano sized tin composite on graphite as anode for lithium ion battery

s03-013

**Chia-Chin Chang** (Department of Greenery Technology, National University of Tainan, Tainan, Taiwan), Tsan-Yao Chen, Pin-Chin Wu, Po-Wei Yang, Yu-Fan Chen, Chih-Wei Hu, Yen-Fa Liao

*In-Situ* X-ray Diffraction on the Lithium-Ion Migrating in Micro-Porous Separator

s03-014

**Long Chen** (Department of Chemistry, Fudan University, Shanghai, China), Wangyu Li, Zhaowei Guo, Yonggang Wang, Congxiao Wang, Yongyao Xia

Aqueous Lithium-Ion Batteries Using  $\text{O}_2$  Self-elimination Polyimides Electrodes

s03-015

**Jian Chen** (Dalian National Laboratory of Clean Energy, Dalian Institute of Chemical Physics, CAS, Dalian, China), Shifeng Yang, Jiao Zhao, Panpan Su, Qihua Yang, Can Li

High Energy Density Electrode Materials Prepared with Metal-Organic Coordination-Polymers for the Applications in LIBs

s03-016

**Hsun-Yi Chen** (Bio-Industrial Mechatronics Engineering, National Taiwan University, Taipei, Taiwan), Chih-Wei Chang, Dong-Yi Chao

Buffer Effects of Electrolyte Additives on Lead-Acid Flow Batteries

s03-017

**Rui Di** (Graduate School of Engineering, Kyoto University, Kyoto, Japan), Kohei Miyazaki, Tomokazu Fukutsuka, Takeshi Abe

Anion Conductivities of Positively-charged Hydroxides with One-dimensional Channel Framework

s03-018

**Chil Hoon Doh** (Battery Research Center, KERI, Korea Electrotechnology Research Institute, Changwon, Korea), You Jin Lee, Adnan Yaqub, Min Ji Hwang, Jeong Hee Choi, Hae Young Choi

Low Temperature Performances of  $\text{LiNi}_{0.6}\text{Co}_{0.2}\text{Mn}_{0.2}\text{O}_2$ /graphite Batteries

s03-019

**Xiaoli Dong** (Department of Chemistry, Fudan University, Shanghai, China), Yonggang Wang, Yongyao Xia  
Re-building Daniell Cell with a Li-ion Exchange Film

s03-020

**Jason Fang** (Material and Chemical Research Laboratories, Industrial Technology Research Institute, Hsinchu, Taiwan)

High Energy Solid State Battery

s03-021

**Tsukasa Gejo** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Shintaro Terui, Masatsugu Morimitsu

High Capacity and High Energy Density of Air Secondary Battery Using Metal Hydride Negative Electrode

s03-022

**Masashi Hattori** (Graduate School of Human and Environmental Studies, Kyoto University, Kyoto, Japan), Kentaro Yamamoto, Koji Nakanishi, Takuya Mori, Titus Mase, Yuki Orikasa, Yukinori Koyama, Zempachi Ogumi, Yoshiharu Uchimoto

Operando X-ray absorption spectroscopic study on magnesium metal anode reaction for magnesium rechargeable battery

s03-023

**Ping He** (College of Engineering & Applied Sciences, Nanjing University, Nanjing, China)

Enabling Catalytic Oxidation of  $\text{Li}_2\text{O}_2$  at Liquid-Solid Interface: A Successful Evolution for an Aprotic  $\text{Li-O}_2$  Battery

s03-024

**Min Young Hong** (Graduate School of Knowledge-based Technology and Energy, Korea Polytechnic University, Siheung-si, Korea), Hyojin Jung, Ji Heon Ryu

Improvement of High-Temperature Performance of the  $\text{LiMn}_2\text{O}_4$  Positive Electrode by the Addition of  $\text{Li}_3\text{PO}_4$

s03-025

**Hui-Yu Hong** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Chao-Yen Kuo, Jian-Ting Chin, Chen-Jui Huang, Men-Che Tsai, Bing-Joe Hwang

Interaction between Carbon Defects and Polysulfides in Lithium Sulfur Battery

s03-026

**Shang-Chieh Hou** (Department of Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan), Chia-Chin Chang, Jow-Lay Huang, Shun-Min Yang

Characterizations and electrochemical properties of high energy mechanical milled Si as anode for Li-ion batteries

s03-027

**Tien-Hsiang Hsueh** (Physics Division, Institute of Nuclear Energy Research, Taoyuan, Taiwan), Chi-Hung Su, Der-Jun Jan, Yuh-Jenq Yu, Yuan-Ruei Jheng

Island-like deposition of lithium manganese oxide spinel ( $\text{LiMn}_2\text{O}_4$ ) in all-solid-state thin film lithium ion battery

s03-028

**Ling Huang** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China)

Tuning structure and *in situ* XRD characterization of Li-rich layered cathode Materials for lithium ion batteries

s03-029

**Meiqi Huang** (Graduate School of Engineering, Kyoto University, Kyoto, Japan), Tomokazu Fukutsuka, Kohei Miyazaki, Akitoshi Hayashi, Masahiro Tatsumisago, Takeshi Abe

Interfacial Lithium-ion Transfer between Graphite Negative Electrode and Sulfide Solid Electrolyte

s03-030

**Sunhyung Jurng** (Department of Chemical and Biological Engineering, Seoul National University, Seoul, Korea), Hyun-seung Kim, Jae Gil Lee, Ji Heon Ryu, Seung M. Oh

Low Temperature Characteristics of Surface Film Derived from Elemental Sulfur Additive on Graphite Negative Electrode

s03-031

**Takehisa Kato** (Department of Materials, Physics and Energy Engineering, Nagoya University, Nagoya, Japan), Shinya Iwasaki, Yuta Yamamoto, Munekazu Motoyama, Yasutoshi Iriyama

Oxide-Based All-Solid-State Rechargeable Lithium Batteries with  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$ -Glass Ceramic Solid Electrolyte Composite Prepared by Aerosol Deposition

s03-032

**Tomáš Kazda** (Department of Electrical and Electronic Technology, Brno University of Technology, Brno, Czech Republic), Jirí Vondrák, Marie Sedlářková, Andrea Fedorková Straková, Marek Slávik, Pavel Eudek

Influence of the Used Carbons and Binders to the Electrochemical Properties of Li-S Cathode

s03-033

**Nam Seon Kim** (R&D Center, Aekyung Chemical Company, Daejeon, Korea), Soo Jung Kim, Dae Won Park, Gwang Sik Choi

The High Performance Silicon Anodes Including New Water Based Binder in Lithium Ion Batteries

s03-034

**Dong-Wan Kim** (School of Civil, Environmental and Architectural Engineering, Korea University, Seoul, Korea), Gwang-Hee Lee, Joosun Kim

Three Dimensional Cu/C/Ge Heterostructured Electrodes for High-performance Li ion Batteries

s03-035

**Jongjung Kim** (Department of Chemical and Biological Engineering, Seoul National University, Seoul, Korea)

Failure mechanism of SiO negative electrode during high temperature storage

s03-036

**Duri Kim** (Graduate School of Knowledge-based Technology and Energy, Korea Polytechnic University, Siheung-si, Korea), Mina You, Ji Heon Ryu

Effect of Electrode Composition on the Electrochemical Performance of the MnO Negative Electrode Materials for Li-ion Batteries

s03-037

**Toshio Kimura** (Department of Materials, Physics and Energy Engineering, Nagoya University, Nagoya, Japan), Munekazu Motoyama, Yasutoshi Iriyama

*In-Situ* SEM Observations of Li Plating/Stripping Reactions through Li-Pt Alloying on a LiPON Electrolyte

s03-038

**Lingbin Kong** (School of Materials Science and Engineering, Lanzhou University of Technology, Lanzhou, China), Yang Li, Maocheng Liu, Xixin Wang, Ming Shi, Jinbei Liu, Long Kang

Template-free synthesis of porous  $\text{Co}_3\text{O}_4$ @C hierarchical structure for high performance lithium-ion batteries

s03-039

**Chao-Yen Kuo** (Department of Chemistry, Institute of Nuclear Energy Research, Taoyuan, Taiwan), Heng-Wei Chiang, Chien-Hong Lin, Hwa-Jou Wei, Bing-Joe Hwang

Application of Amorphous Carbon-Coated Electrodes in Vanadium Redox Flow Battery

s03-040

**Liang-Yin Kuo** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan)

Highly Stable Sn-C Nanocomposite as an Anode Material for Lithium ion Batteries

s03-041

**Song-Zhu Kure-Chu** (Department of Chemistry and Bioengineering, Iwate University, Morioka, Japan), Haruki Sakuyama, Hitoshi Yashiro, Kuniaki Sasaki, Hiroyo Segawa, Kenji Wada, Satoru Inoue

Facile Formation of 3D Nanoporous Anodic  $\text{TiO}_2$ -TiN Composite Films as Anode Materials for Lithium Rechargeable Batteries

s03-042

**Matthew Lacey** (Department of Chemistry, Ångström Laboratory, Uppsala University, Uppsala, Sweden), Kristina Edström, Daniel Brandell

Detailed “Mapping” of Internal Resistance in Li-S Batteries

s03-043

**Chen-Hsuan Lai** (Materials Science and Engineering, National Dong Hwa University, Hualien, Taiwan), Ing-Song Yu, Fa-Hsing Yeh

Silicon-carbon anode by plasma enhanced chemical vapor deposition for lithium-ion batteries

s03-044

**Jae Gil Lee** (Department of Chemical and Biological Engineering, Seoul National University, Seoul, Korea), Jongjung Kim, Jeong Beom Lee, Hosang Park, Tae-jin Lee, Ji Heon Ryu, Seung M. Oh

A quantitative analysis on the failure mechanism of nano-Si electrode and the effect of fluoroethylene carbonate

s03-045

**Won Jae Lee** (Battery Research Center, KERI, Korea Electrotechnology Research Institute, Changwon, Korea), Yong Hwan Gwon, Seong Ju Sim, You Jin Lee, Doo Hun Kim, Chil Hoon Doh

The performance of All Solid State Li ion Battery with Composite Sulfide Solid Electrolyte

s03-046

**Zhaohui Li** (Chemistry, Xiangtan University, Xiangtan, China), Kailing Sun, Can Peng, Xiaozhen Xiao, Gangtie Lei

Hybrid  $V_2O_5/C$  coated Li- rich manganese-based solid solution and its improved electrochemical properties

s03-047

**Zhaohui Li** (Chemistry, Xiangtan University, Xiangtan, China), Wenjun Li, Chenlu Yang, Xiaozhen Xiao, Gangtie Lei

A batwing-like  $SiO_2/PVdF-g-PMMA$  membrane for high-performance lithium-ion batteries

s03-048

**Jun-Tao Li** (College of Energy, Xiamen University, Xiamen, China), Jie Liu, Zhan-Yu Wu, Tao Zhang, Ling Huang, Shi-Gang Sun

Guar Gum as the Binder for Si Anode of Lithium-Ion Battery

s03-049

**Ximeng Li** (Graduate School of Engineering, Kyoto university, Kyoto, Japan), Shohei Maruyama, Kohei Miyazaki, Tomokazu Fukutsuka, Takeshi Abe

Ion Transport in Graphite Composite Electrode

s03-050

**Chi-Ying Vanessa Li** (Dept of Chemistry, The University of Hong Kong, Hong Kong, China), Ching-Kit Ho, Zhao-Feng Deng, Kwong-Yu Chan

Durable Mesoporous Core-Shell Lithium Titanate-Carbon Composite as Anode in Lithium ion Batteries

s03-051

**Biao Li** (College of Engineering, Peking University, Beijing, China), Huijun Yan, Li An, Hang Wei, Jin Ma

Tuning the Electronic Structure of Layered Oxides Electrodes for Reversible Anionic Redox in Lithium Ion Batteries

s03-052

Dynamics of the Phase Transition Behavior of the  $\text{LiFePO}_4$  Investigated by Time-resolved X-ray Diffraction at Various Temperatures

s03-105

**Hao-Ting Peng** (Chemical Engineering, Tatung University, Taipei, Taiwan), Pei-Sin Yin, Jeng-Yu Lin  
High-performance lithium-ion batteries based on  $\text{C Li}_4\text{Ti}_{4.95}\text{Al}_{0.05}\text{O}_{12}$  anode materials

s03-106

**Neeraj Sharma** (School of Chemistry, UNSW Australia, Sydney, Australia)  
The structural evolution of cathode materials in the current generation of commercial lithium-ion batteries

### Novel electrode materials and electrode/electrolyte interfaces - theory

s03-107

**Gaukhar Askarova** (Chemistry and Chemical Technology, Al-Farabi Kazakh National University, Almaty, Kazakhstan)  
Development of Charge Transport Model in Composite Polymer Electrolytes

s03-108

**Heng-Wei Chiang** (Department of Chemistry, Institute of Nuclear Energy Research, Taoyuan, Taiwan), Chao-Yen Kuo, Chien-Hong Lin  
Modified Carbon Felt *via* a Facile Oxidation Treatment as an Efficient Electrode for a Vanadium Redox Flow Battery

s03-109

**Yu-Ju Chien** (Chemical Engineering, National Tsing Hua University, Hsin-Chu City, Taiwan)  
Synthesis of Ternary Spinel Iron-Cobalt-Nickel Oxide/Carbon Black Composites as a High-Performance Bifunctional Electrocatalyst for Rechargeable Zinc-Air Batteries

s03-110

**Josh Y. Z. Chiou** (Department of Materials Engineering, Tatung University, Taipei, Taiwan), Shou-Huang Su  
Structural Effects of Spinel  $\text{LiMn}_{1.5}\text{Ni}_{0.5}\text{O}_4$  on Their Electrochemical Properties

s03-111

**Ahmad Fauzan Adziimaa** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan), Fu-Ming Wang  
Combination effects of graphene oxide as carbon black and maleimide as electrolyte additive in lithium ion batteries

s03-112

**Giyanto Giyanto** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan), Fu-Ming Wang  
The electronegativity effects of maleimide based electrolyte additives in SEI formation of lithium ion battery

s03-113

**Xiaoyan Hu** (Chemistry Department, Xiamen University, Xiamen, China), Bingwei Mao  
*In-situ* STM characterization of ionic liquids on Au(111) and HOPG electrodes in the presence of lithium salt

s03-114

**Xiao Huang** (Department of Chemistry, BMC, Uppsala University, Uppsala, Sweden), Li Yang, Maria Stromme, Adolf Gogoll, Martin Sjödin  
Synthesis and Redox Properties of Thiophene-Terephthalate Building Blocks for Low Potential Conducting Redox Polymers

s03-115

**Hyuntak Jo** (Energy Science and Technology, Chungnam National University, Daejeon, Korea), Xuan Minh Tran, Dan-Thien Nguyen, Hyo Ki Hwang, Kil Ku Kang, Seung-Wan Song  
Correlation between Interfacial Reaction Behavior and Cycling Characteristics of Silicon-based Anodes in Li-ion Batteries

s03-116

**Shingo Kaneko** (Research Institute for Engineering, Kanagawa University, Yokohama, Japan), Yuichi Sato, Futoshi Matsumoto, Junwei Zheng, Decheng Li

Size-regulated Precursor-Based Synthesis of Lithium-Rich Layered Cathode Material Deriving High Rate Capability

s03-117

**Donghyun Kil** (Department of Chemical and Biomolecular Engineering, Yonsei University, Seoul, Korea), Hansung Kim

Development of short-termed and highly effective graphite felt surface treatment process for all-vanadium redox flow battery applications

s03-118

**Joon soo Kim** (Advanced Materials and Devices Laboratory, Korea Institute of Energy Research, Daejeon, Korea), Bo yun Jang, Jin Seok Lee, Jeong Boon Koo, Jeong Eun Lee

Synthesis of Si Nanoparticles by Atmospheric Microwave Plasma

s03-119

**Richard Kloepsch** (MEET Battery Research Center, University of Muenster, Muenster, Germany), Jatinkumar Rana, Gerhard Schumacher, John Banhart, Martin Winter, Jie Li

Investigation of surface and bulk structural modifications in Li/Mn-rich cathode materials of Li-ion batteries using X-ray absorption spectroscopy

s03-120

**Hwa Jin Lee** (School of Chemical Engineering, University of Ulsan, Ulsan, Korea), Seul Lee, Eun-Suok Oh

Application of modified rosin-derivatives as promising adhesives for lithium titanium oxide electrodes in lithium ion batteries

s03-121

**Tae-jin Lee** (Department of Chemical and Biological Engineering, Seoul National University, Seoul, Korea), Taeho Yoon, Jiwon Jung, Jiyong Soon, Jae Gil Lee, Ji Heon Ryu

A comparative study on Li<sup>+</sup> ion migration characteristics in the interphases of positive and negative electrodes

s03-122

**Jeong Beom Lee** (Department of Chemical and Biological Engineering, Seoul National University, Seoul, Korea), Janghyuk Moon, Oh B. Chae, Ji Heon Ryu, Maenghyo Cho, Kyeongjae Cho, Seung M. Oh

Combined Theoretical *Ab-initio* and Experimental Study on LiVO<sub>3</sub>, A Novel Conversion-type Negative Electrode for Lithium-ion Batteries

s03-123

**Shih-kang Lin** (Department of Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan), Ping-chun Tsai, Wen-Dung Hsu

*Ab initio*-aided Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> defect spinel electrode materials designs for durable lithium ion batteries

s03-124

**Arailym Nurpeisova** (Graduate School of Energy Science and Technology, Chungnam National University, Daejeon, Korea), Da-In Park, Sung-Soo Kim

SEI stabilizer agent epicyanohydrin for cathodes used in LIBs

s03-125

**Sangki Park** (Department of Chemical and Biomolecular Engineering, Yonsei University, Seoul, Korea), Hansung Kim

Polypyrrole as the Coating Agent and Nitrogen Precursor for the Fabrication of Nitrogen-Doped Graphite Felts as Positive Electrode for a Vanadium Redox Flow Battery

s03-126

**Hao-Ting Peng** (Chemical Engineering, Tatung University, Taipei, Taiwan), Cheng-Yao Lee, She-huang Wu, Jeng-Yu Lin

Effects of electrolyte additive on the electrochemical properties of lithium-ion batteries based on Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> anode materials

s03-127

**Joaquin Rodriguez-Lopez** (Department of Chemistry, University of Illinois at Urbana-Champaign, Urbana, USA), Elena Catalina Montoto Blanco, Jingshu Hui, Nagarjuna Gavvalapalli, Etienne Chenard, Kevin Cheng, Timothy Lichtenstein, Jeffrey Moore

Redox Active Polymers: Pursuing a Size-Selective Strategy for High Performance Non-Aqueous Redox Flow Batteries

s03-128

**Hayate Saito** (IMRAM, Tohoku University, Sendai, Japan), Daiki Komatsu, Takaaki Tomai, Itaru Honma  
Capacity enhancement of semi-solid flow capacitor using quinonic compounds

s03-129

**Sébastien Sallard** (Electrochemistry Laboratory, Paul Scherrer Institut, Villigen-PSI, Switzerland), Sebastian Schmidt, Denis Sheptyakov, Petr Novak, Claire Villevieille  
Lithium iron methylene diphosphonate, a new organic-inorganic hybrid material for Li-ion batteries.

s03-130

**Selina Tillmann** (MEET Battery Research Center, University of Muenster, Muenster, Germany), Martin Winter, Isidora Cekic-Laskovic  
Electrodeposition of Silicon for the Preparation of Submicrostructured Electrodes

s03-131

**Roberto Torresi** (Instituto de Química, Universidade de São Paulo, São Paulo, Brazil), Vitor L. Martins, Nédher Sanchez-Ramirez, Mauro C. C. Ribeiro  
Transport properties of Li<sup>+</sup> Mixtures in Two Phosphonium Containing Ionic Liquids

s03-132

**Gang Wang** (School of Chemistry and Chemical Engineering, Shihezi University, Shihezi City, China), Yongtao Zuo, Jun Peng, Gang Li, Feng Yu, Bin Dai, Xuhong Guo  
Hybridization of graphene sheets and carbon-coated Fe<sub>3</sub>O<sub>4</sub> hollow nanoparticles as a high-performance anode material for lithium-ion batteries

s03-133

**Gang Wang** (School of Chemistry and Chemical Engineering, Shihezi University, Shihezi City, China), Jun Peng, Yongtao Zuo, Gang Li, Feng Yu, Bin Dai, Xuhong Guo  
*In situ* polyol-assisted synthesis of Zn<sub>2</sub>SnO<sub>4</sub> nanocrystals/graphene nanohybrid as high-performance anode for Li-ion batteries

s03-134

**Nan Hung Yeh** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan), Lyu Ye Yang, Fu-Ming Wang  
Next generation of Self Terminated Oligomer Branched Architecture (STOBA) in Li-rich (Li<sub>1.2</sub>Ni<sub>0.2</sub>Mn<sub>0.6</sub>O<sub>2</sub>) high capacity cathode material of lithium ion battery

s03-135

**Aishui Yu** (Chemistry Department, Fudan University, Shanghai, China)  
Three-Dimensional Activated Porous Carbon /Sulfur Composites as Cathode Materials for Lithium-Sulfur Batteries

s03-136

**Ludan Zhang** (Chemistry, Fudan University, Shanghai, China)  
Carbon-coated Na<sub>3</sub>V<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> Nanocomposite as a Novel High Rate Cathode Material for Aqueous Sodium Ion Batteries

s03-137

**Qianyu Zhang** (Key Laboratory of Renewable Energy, Guangzhou Institute of Energy Conversion, Chinese Academy of Sciences, Guangzhou, China), Chuying Ouyang, Lingzhi Zhang  
W<sup>6+</sup>&Br-codoped Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> Anodes with Super Rate Performance

s03-138

**Wenli Zhang** (College of Chemistry, Jilin University, Changchun, China), Jian Yin, Zheqi Lin, Haibo Lin, Haiyan Lu, Yue Wang, Jinpeng Bao, Tingting Liu  
Mechanisms of Activated Carbon in Lead-Carbon Battery

s03-139

**Haoliang Zhong** (Guangzhou Institute of Energy Conversion, Chinese Academy of Sciences, Guangzhou, China), Lingzhi Zhang  
Carboxymethyl Chitosan/Poly(ethylene oxide) as a Water Soluble Blend Binder for 5 V LiNi<sub>0.5</sub>Mn<sub>1.5</sub>O<sub>4</sub> Cathodes with Improved Cycle Stability in Li-Ion Batteries

s03-140

**Dauren Batyrbekuly** (Institute of Batteries, Institute of Batteries, Astana, Kazakhstan), Almagul Mentbayeva, Yongguang Zhang, Indira Kurmanbayeva, Kuralay Korzhynbayeva, Zhumabai Bakenov  
Reinforced composite gel-polymer electrolytes for lithium-sulfur batteries

## Symposium 4: Advances in Fuel Cells from Materials to Systems

### Ageing and degradation

s04-001

**Daniel Garcia** (Electrochemical Energy Technology, Deutsches Zentrum für Luft- und Raumfahrt (DLR), Stuttgart, Germany)

Comparison of the Degradation process during the bus application loading cycling in PEMFC

s04-002

**Misako Ikeyama** (Graduate School of Engineering, Oita University, Oita, Japan), Taro Kinumoto, Sawaka Kitayama, Miki Matsuoka, Tomoki Tsumura, Masahiro Toyoda

IL-FE-SEM Study for Ambience Dependence of Degradation of Pt/C Catalyst

s04-003

**Timothy J. Peckham** (Department of Chemistry, Simon Fraser University, Burnaby, Canada), Lida Ghassemzadeh, Thomas Weissbach, Xiaoyan Luo, Steven Holdcroft

Structure and Property Changes of PFSA Ionomer Upon Exclusive Reaction with HO and H Radicals

s04-004

**Mirosław Stygar** (Faculty of Materials Science and Ceramics, AGH University of Science and Technology, Krakow, Poland), Juliusz Dabrowa, Tomasz Brylewski

Oxidation kinetics and microstructure of oxide products formed on the Crofer 22APU ferritic stainless steel in a dual atmosphere

s04-005

**Lung-Yu Sung** (Energy storage Department, Industrial Technology Research Institute, Hsinchu, Taiwan)

Effects of H<sub>3</sub>PO<sub>4</sub> leaching on the performance and degradation of high temperature-proton exchange membrane fuel cells

### Direct alcohol fuel cells

s04-006

**Patricia Corradini** (Instituto de Química de São Carlos, Universidade de São Paulo, São Carlos, Brazil), Nathalia Santos, Valdecir Paganin, Ermete Antolini, Joelma Perez

Synthesis and characterization of electrocatalysts PtSnEu/C for anode in direct alcohol fuel cell

s04-007

**Lin Gan** (Division of Energy and Environment, Graduate school at Shenzhen, Tsinghua University, Shenzhen, China), Lingyi Peng, Hao Yang, Jia Li, Hongda Du

Role of Interfaces of Au@Pt Nanoparticles in the Electrocatalysis of Alcohol Oxidation

s04-008

**Xuan Zhang** (College of Chemistry, Chemical Engineering & Biotechnology, Donghua University, Shanghai, China), Jia-Wei Zhang, Bei Zhang

Improving the Electrocatalytic Activity of Binary Alloy Cu<sub>x</sub>Pd<sub>y</sub> for Methanol Oxidation Reaction by Tailoring Chemical Composition

### Electrolysis

s04-009

**Tae-Hyun Yang** (Fuel Cell Research Center, Korea Institute of Energy Research, Daejeon, Korea), Young-Jun Sohn, Minjin Kim

Simulated Design of High-altitude Long-endurance Unmanned Aerial Vehicles using Regenerative Fuel Cell Systems

### Fuel cell and electrolysis membranes and separators

s04-010

**Min-Hsing Chang** (Mechanical Engineering, Tatung University, Taipei, Taiwan), Sheng-Wei Huang

Fabrication of Anode Microporous Layer with Carbon Nanotubes and its Effect on Proton Exchange Membrane Fuel Cell Performance

s04-011

**Ping-Yen Chen** (Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan)

Novel Polybenzimidazoles Containing Bulky Side Groups for High-temperature Polymer Electrolyte Membranes Fuel Cell Applications

s04-012

**Nick Daems** (Centre for Surface Chemistry and Catalysis, K.U. Leuven, Heverlee, Belgium), Sam Milis, Paolo Pescarmona, Ivo Vankelecom

Synthesis of membrane electrode assemblies for proton-exchange membrane fuel cells

s04-013

**Ronghuan He** (Department of Chemistry, College of Sciences, Northeastern University, Shenyang, China), Yixin Xu, Jingshuai Yang

Cross-Linked Imidazolium-Based Anion Exchange Membranes

s04-014

**Xiangnan He** (Chemistry, Northeastern University, Shenyang, China)

Bi-imidazolium Cation Crosslinked Poly(2,6-dimethyl-1,4-phenylene oxide) Anion Exchange Membranes for Fuel Cell Application

s04-015

**Wang Hsiang-Cheng** (School of Defense Science, CCIT, National Defense University, Taoyuan, Taiwan), Ger Ming-Der, Lu Chen-En

Improvement on corrosion resistance and conductivity by electroplated coatings on aluminum 5052 bipolar plate of proton exchange membrane fuel cell

s04-016

**Taro Kimura** (Graduate School of Medicine and Engineering, University of Yamanashi, Kofu, Japan), Masanori Hara, Junji Inukai, Makoto Uchida, Manai Shimada, Hideaki Ono, Shigefumi Shimada, Kenji Miyatake, Masahiro Watanabe

Anion-conductive areas on anion exchange membranes analyzed by current-sensing atomic force microscopy under controlled conditions

s04-017

**Dong-Hoon Lee** (Green Materials Research Group, Youngin, Korea), Eun-Su Lee, Nayoung Kim, Moo-Seok Lee

Development of Nanofiber Reinforced PEM Impregnated with Hydrocarbon Polymer Electrolytes

s04-018

**Hyejin Lee** (Fuel Cell Laboratory, Korea Institute of Energy Research (KIER), Daejeon, Korea), Byungchan Bae

Proton Conducting Composite Membranes with Improved Oxidative Stability for PEMFC

s04-019

**Sojeong Lee** (Fuel Cell Laboratory, Daejeon, Korea), Byungchan Bae

Crosslink-free highly sulfonated multi-block poly(arylene ether sulfone) multi-block membranes for PEMFC

s04-020

**Shih-Wei Lee** (Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Jin-An Wu, Kuei-Hsien Chen

Novel Poly(ether sulfones) with Clustered Sulfonic Groups for PEMFC Applications at Various Relative Humidity

s04-021

**Kwangjin Oh** (Energy Systems Engineering, Daegu Gyeongbuk Institute of Science and Technology, Daegu, Korea)

Synthesis of sulfonated block copolymer for polymer electrolyte fuel cells operating at intermediate temperature

s04-022

**Gyu-Hyeon Oh** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Mun-Sik Shin, Moon-Sung Kang, Jin-Soo Park

Effects of Solvents for Dispersion Solutions on Membrane-Electrode Assembly for Proton Exchange Membrane Fuel Cells – Overvoltage and Durability

s04-023

**Mun-Sik Shin** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Jin-Soo Park

The Porous Polyimide Membranes Derived from Diamine Monomer Containing Benzimidazole Unit for High Temperature Fuel Cells

s04-024

**Mun-Sik Shin** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Moon-Sung Kang, Jin-Soo Park

Preparation and Characterization of Anion Conducting Ionomer Binder based on Quaternized Polybenzimidazole for Solid Alkaline Fuel Cells

## Fuel cell electrocatalysis

s04-025

**Koki Baba** (Department of Biomolecular Functional Engineering, Ibaraki University, Ibaraki, Japan), Mika Shiraishi, Risa Shiraishi, Mikka Nishitani-Gamo, Toshihiro Ando, Mika Eguchi

Enhancement of polymer electrolyte fuel cell performance using a Marimo carbon

s04-026

**Antoinette Boreave** (Chemistry, CNRS, Villeurbanne, France), Foteini M. Sapountzi, Michail N. Tsampas, Chunhua Zhao, Laurence Retailleau, Dario Montinaro, Philippe Vernoux

Triode Operation for Enhancing the Performance of H<sub>2</sub>S-Poisoned SOFCs for CH<sub>4</sub> Steam Reforming

s04-027

**Kuo-Wei Chiang** (Department of Chemical Engineering and Materials Science, Yuan Ze University, Taoyuan, Taiwan), Bo-Syun Cheng, Ken-Ming Yin

Mathematical Model of Non-Uniform Cathode Catalytic Layer on the Performance of PEMFC

s04-028

**Xiaoqiang Cui** (School of Materials Science and Engineering, Jilin University, Changchun, China)

Plasmonic Induced Inhibition and Enhancement of the Electrocatalytic Activity for Ethanol Oxidation on Pd/Au Hetero-Nanoraspberries

s04-029

**He-yun Du** (Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan), Li-Chyong Chen, Kuei-Hsien Chen, Chen-Hao Wang

Enhanced Proton Conductivity of Polybenzimidazole Membranes Synthesized *via* Direct-casting Process for High Temperature Fuel Cells

s04-030

**Kazuma Furuhashi** (Department of Biomolecular Functional Engineering, Ibaraki University, Hitachi, Japan), Mika Shiraishi, Risa Shiraishi, Mikka Nishitani-Gamo, Toshihiro Ando, Mika Eguchi

Electrochemical characterization of Marimo carbon supported Pt–Pd

s04-031

**Daniel Garcia** (Institut für Technische Thermodynamik, Deutsches Zentrum für Luft und Raumfahrt (DLR), Stuttgart, Germany), Beatriz Martinez, J.L Castillo, Kaspar Andreas Friedrich, P.L Garcia-Ybarra

Characterization of ultra-low loading MEAs fabricated by electrospray deposition

s04-032

**Valentina Grippo** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Roland Ludwig, Renata Bilewicz

Comparison of fuel cells based on different cathode and anode enzymes

s04-033

**Makoto Hamazaki** (Green Hydrogen Research Center, Yokohama National University, Yokohama, Japan), Akimitsu Ishihara, Yuji Kohno, Koichi Matsuzawa, Shigenori Mitsushima, Kenichiro Ota

Evaluation of durability of titanium-niobium oxides mixed with Ti<sub>4</sub>O<sub>7</sub> as non-precious metals and carbon-free cathodes for PEFC in sulfuric acid at 80°C

s04-034

**Akari Hayashi** (International Research Center for Hydrogen Energy, Kyushu University, Fukuoka, Japan), Yasuto Minamida, Zhiyun Noda, Kazunari Sasaki

Development of a cathode material for durable PEFC through the encapsulation of Pt into carbon mesopores

s04-035

**Hsiao-Chun Huang** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Chun-Jern Pan, Wei-Nien Su, Bing-Joe Hwang

Conductive oxide supported Co<sub>3</sub>O<sub>4</sub> nanocomposite as robust catalysts for oxygen reduction and evolution reaction

s04-036

**Xuan Jian** (College of Chemistry and Chemical Engineering, Taiyuan University of Technology, Taiyuan, China), Xian Liu, Huimin Yang, Zhenhai Liang

Graphene-Carbon Nanofibers Composite Film As a Highly Active Catalyst Support for Formic Acid Electrooxidation

s04-037

**Nozomi Kawakami** (Department of Chemical Engineering, National Institute of Technology, Nara College, Yamatokoriyama, Japan), Hirohisa Yamada, Takanori Kobayashi, Zyun Siroma, Katsumi Katakura, Minoru Inaba

Fundamental Studies on Oxygen Reduction Reaction and Hydrogen Peroxide Reduction Reaction with RRDE Technique

s04-038

**Marika Muto** (Graduate School of Environmental Science, Hokkaido University, Sapporo, Japan), Masaru Kato, Ichizo Yagi

Copper-Incorporated Carbon Catalysts for Oxygen Reduction Reaction

s04-039

**Tsukasa Nagai** (Research Institute of Electrochemical Energy, AIST, Osaka, Japan), Shin-ichi Yamazaki, Naoko Fujiwara, Masafumi Asahi, Zyun Siroma, Tsutomu Ioroi

Metalloporphyrin-Modified Perovskite-Type Oxide for Cathode Catalyst in Alkaline Fuel Cell

s04-040

**Aziz Nechache** (Division of Physical Sciences and Engineering, King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia), Samir Boulfrad, Shahid P. Shafi, Enrico Traversa

La<sub>0.2</sub>Sr<sub>0.25</sub>Ca<sub>0.45</sub>Ti<sub>1-x</sub>yNb<sub>x</sub>Ni<sub>y</sub>O<sub>3</sub> as Potential Anode Material for IT-SOFCs

s04-041

**Yao Nie** (School of Chemistry and Chemical Engineering, Chongqing University, Chongqing, China), Siguo Chen, Wei Ding, Xiaohong Xie, Yun Zhang, Zidong Wei

Pt/C Trapped in Activated Graphitic Carbon Layers as a Highly Durable Electrocatalyst for Oxygen Reduction Reaction

s04-042

**Kazuma Shinozaki** (Chemistry, Colorado School of Mines, Golden, USA), Shyam Kocha

Rotating Disk Electrode Studies on the Effect of Nafion on the Oxygen Reduction Reaction for Pt/C and Pt Alloy/C

s04-043

**Ryo Shirasaka** (Chemical Engineering, Tokyo National College of Technology, Hachioji, Japan), Sakumi Aoyagi, Hidenobu Shiroishi, Keiji Nagai, Hiraku Ota, Mikka Nishitani-Gamo

Effect of dispersion methods on oxygen reduction and ammonia oxidation activity for a MWCNT supported Pt catalyst

s04-044

**Hidenobu Shiroishi** (Chemical Science and Engineering, Tokyo National College of Technology, Hachioji, Japan), Genki Horiguchi, Yu Chikaoka, Masato Uehara, Naoki Matsuda

Synthesis of Pt Nanoparticles using Microbubble-assisted Low-Voltage Low Frequency Solution Plasma Processing

s04-045

**Yuko Tamura** (Green Hydrogen Research Center, Yokohama National University, Yokohama, Japan), Akimitsu Ishihara, Yuji Kohno, Koichi Matsuzawa, Shigenori Mitsushima, Kenichiro Ota

Titanium-niobium oxides as non-platinum cathodes for polymer electrolyte fuel cells

**Oxygen evolution/reduction reactions**

s04-046

**Wei Ding** (School of Chemistry and Chemical Engineering, Chongqing University, Chongqing, China), Wei Li, Guangping Wu, Li Li, Siguo Chen, Xueqiang Qi, Zidong Wei

Shape Fixing *via* Salt Recrystallization: A Morphology-Controlled Approach to Convert Nanostructured Polymer to Carbon Nanomaterial as a High Active Catalyst for Oxygen Reduction Reaction

s04-047

**Monika Góral-Kurbiel** (Jerzy Haber Institute of Catalysis and Surface Chemistry PAS, Kraków, Poland), Alicja Drelinkiewicz, Robert Kosydar, Jacek Gurgul, Beata Dembińska, Pawel J. Kulesza, Elzbieta Bielańska, M. Ruggiero

The Effect of Nafion Ionomer on Electroactivity of Palladium-Polypyrrole Catalysts for Oxygen Reduction Reaction

s04-048

**Tomoaki Hayashi** (Green Hydrogen Research Center, Yokohama National University, Yokohama, Japan), Akimitsu Ishihara, Yuji Kohno, Koichi Matsuzawa, Shigenori Mitsushima, Kenichiro Ota

Kinetics of oxygen reduction reaction on titanium oxide-based catalysts prepared from oxy-titanium tetra-pyrazino-porphyrizine in acidic media

s04-049

**Zi-Jun Lin** (Institute of Materials Science and Engineering, National Central University, Taoyuan, Taiwan), Hong-Shou Chen, Yu-Ting Liang, Kuan-Wen Wang

The Effect of Heat-Treatment on the Oxygen Reduction Reaction Activity of Carbon-Supported PtCoAg Electrocatalysts

s04-050

**Yuta Nabae** (Department of Organic and Polymeric Materials, Tokyo Institute of Technology, Meguro-ku, Japan), Teruaki Hayakawa, Hideharu Niwa, Yoshihisa Harada, Masaharu Oshima, Atsushi Matsunaga, Ayano Isoda, Kazuhisa Tanaka

Synthesis and Characterization of Carbon-Based Non-Precious-Metal Cathode Catalysts from Polyimide Fine Particles

s04-051

**Chen-Yu Tsai** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Yi-Chen Wu, Men-Che Tsai, Chun-Jern Pan

Preparation of Highly Conductive TiO<sub>2</sub> Supported Pt Catalyst and Its Electrochemical Performance

**Physical electrochemistry**

s04-052

**Yongli Zheng** (Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China, Hefei, China), Yanxia Chen, Zhengda He, Jie Wei

The Degradation of Oxygen Reduction Activity at Stepped Platinum Surfaces in Acidic Media

s04-053

**Yongli Zheng** (Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China, Hefei, China), Yao Yao, Dong Mei, Yanxia Chen

Oxygen reduction reaction on Au@Pt nanoparticles and Au(100) electrode

**Solid oxide cells**

s04-054

**Junfu Bu** (Department of Materials Science and Engineering, KTH Royal Institute of Technology, Stockholm, Sweden), Pär Jönsson, Zhe Zhao

The Effect of NiO on the Conductivities of BaZr<sub>x</sub>Ce<sub>0.8-x</sub>Y<sub>0.2</sub>O<sub>3-δ</sub> (x = 0.5, 0.6, 0.7, 0.8) Proton Conductors

s04-055

**Zhao Hui** (Chemistry, Heilongjiang University, Harbin, China)

Electrochemical performance of double perovskite Pr<sub>2</sub>NiMnO<sub>6</sub> as cathode for intermediate temperature solid oxide fuel cells

s04-056

**I-Ming Hung** (Department of Chemical Engineering and Materials Science, Yuan Ze University, Taoyuan, Taiwan), Hao-Ying Cheng, Sheng-Wei Lee, Jeng-Kuei Chang, Jing-Chie Lin, Jason Shian-Ching Jang, Chuan Li, Chi-Shiung Hsi

Synthesis and Characterization of High Temperature Proton Conductor  $\text{Sr}(\text{Ce}_{0.6}\text{Zr}_{0.4})\text{O}_{3-\delta}$  co-doped with Indium and Yttrium

s04-057

**Sou Ikeda** (Department of Hydrogen Energy Systems, Kyushu University, Fukuoka, Japan), Shota Kotake, Hironori Nakajima, Tatsumi Kitahara

Mass Transfer Analysis of Anode-Supported Honeycomb Solid Oxide Fuel Cells

s04-058

**Yuya Kitaguchi** (Chemical Engineering, National Institute of Technology, Nara College, Yamatokoriyama, Japan), Hirohisa Yamada, Katsumi Katakura

Study on Ion conductivity of Mg-Al Layered Double Hydroxides prepared by electrochemical co-precipitation method

s04-059

**Aditya Maheshwari** (Institute of Inorganic Chemistry, University of Muenster, Muenster, Germany), Hans-Dieter Wiemhöfer

A Novel Approach to Develop MIEC material:  $\text{CeO}_2\text{-ZrO}_2$  composite

s04-060

**Chung-Ta Ni** (Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan), Shu-Yi Tsai, Kuan-Zong Fung, Yu-Cheng Su, Han-Lung Liu

Structural Stability of Mixed Conducting  $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$  ( $x=0\sim0.4$ ) Perovskite in Different Atmospheres

s04-061

**Chung-Ta Ni** (Research Center for Energy Technology and Strategy, National Cheng Kung University, Tainan City, Taiwan), Shu-Yi Tsai, Kuan-Zong Fung, Hsin-Chia Ho

Effect of Thermal Effect on Phase Transformation of Plasma Sprayed Protective Oxides on SOFC Metallic Interconnects

s04-062

**Masanori Ochi** (Applied Physics, Tokyo University of Science, Tokyo, Japan), Shohei Yamaguchi, Takaaki Suetsugu, Naoya Suzuki, Kinya Kawamura, Takashi Tsuchiya, Masaki Kobayashi, Hiroshi Kumigashira, Tohru Higuchi

Structural and Electrical properties of Ru-doped  $\text{BaCe}_{0.90}\text{Y}_{0.10}\text{O}_{3-\delta}$  Thin Film

s04-063

**Mirosław Stygar** (Faculty of Materials Science and Ceramics, AGH University of Science and Technology, Krakow, Poland), Waldemar Tejchman, Juliusz Dabrowa, Tomasz Brylewski

Preparation and structural and electrical properties of calcium-doped and nickel-doped yttrium chromate(III)

s04-064

**Shu-Yi Tsai** (Research Center for Energy Technology and Strategy, National Cheng Kung University, Tainan City, Taiwan), Kuan-Zong Fung, Chung-Ta Ni, Yu-Fan Chang

Effect of Composite Cathode on Polarization Reduction for Solid Oxide Fuel Cells based on Microstructure and Ion-Conduction Consideration

## Symposium 5: Novel Insights to Electrochemical Capacitors

### Edl capacitor

s05-001

**Mohammad BinSabt** (Chemistry, Faculty of Science, Kuwait University, Kuwait, Kuwait), Ahmed Abdel Nazeer, Ahmed Galal

Effect of Nickel Oxide Type on the Electrochemical Behavior of Nickel-Graphene Oxide Hybrid – Towards Electrochemical Capacitor

s05-002

**Hsiu-Chuan Chien** (Chemical Engineering, National Tsing Hua University, Hsin-Chu City, Taiwan)

Buffer Effect on Electrolytes towards Supercapacitors Application

s05-003

**Hui Dou** (College of Material Science and Engineering, Nanjing University of Aeronautics and Astronautics, Nanjing, China), Guiyin Xu, Qi Sheng, Bing Ding, Aixiu Wang, Zhi Chang

Porous Carbon Nanofiber with Phosphorus and Nitrogen Dual-Doping for High Performance Supercapacitors

s05-004

**Hsin-Chieh Huang** (Department of Chemical Engineering, National Cheng Kung University, Tainan, Taiwan), Hsisheng Teng

Facile Fabrication of High-Performance All-Solid-State Micro-supercapacitors through Laser Micromachining

s05-005

**Pawel Jezowski** (Institute of Chemistry and Technical Electrochemistry, Poznan University of Technology, Poznan, Poland), François Béguin

Activated carbon electrode expansion during EDL charging in various salt aqueous electrolytes

s05-006

**Ick-Jun Kim** (Battery Research Center, Korea Electrotechnology Research Institute, Changwon Si, Korea)

Effects of joule-heating on the activated carbon for improved electric double layer capacitor

s05-007

**Chunling Liu** (School of Chemistry and Chemical Engineering, Shaanxi Normal University, Xi'an, China), Yana Li, Li Wang, Fajun Xia, Tong Yang, Wensheng Dong

Ordered mesoporous carbon nitride as an electrode material for high performance electrochemical capacitors

s05-008

**Jiayun Liu** (Environmental Engineering, Donghua University, Shanghai, China), Miao Lu, Jianmao Yang, Jian Cheng, Wenshu Cai, Zhubiao Xiong

Asymmetric Capacitors to Improve the Charge Efficiency of the Capacitive Deionization

s05-009

**Mahmoud Mohamed Mahmoud Ahmed** (Graduate Institute of Applied Science and Technology, NTUST, Taipei, Taiwan), Toyoko Imae, Masaki Ujihara

Nondestructive production of magnetic graphene towards energy applications

s05-010

**Sung June Park** (Department of Energy Systems Research, Ajou University, Suwon, Korea), Jaeshin Yi, Kyung-Seok Min, Jongrak Choi, Ha-Young Lee

Thermal modeling of an ultracapacitor module for automotive applications

s05-011

Surface Textured Silicon Photocathode for  $\text{H}_2$  Production Improves Photoelectrochemical Water Splitting efficiency

s06-009

**Shu-Yi Tsai** (Department of Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan), Chung-Ta Ni, Kuan-Zong Fung

Infrared transparent  $\text{NiCo}_2\text{O}_4$  thin film as a Front Electrode for Solar Cells

s06-010

**Nan Zhang** (Chemistry, Xiamen University, Xiamen, China), Changjian Lin, Miaoqiang Lv, Meidan Ye, Dajiang Zheng

Rutile  $\text{TiO}_2$  Nanosheet Arrays on Thermally Oxidized  $\text{TiO}_2$  Blocking Layer for Enhancing Efficiency of Perovskite Solar Cells

**Photovoltaic**

s06-011

**Wahyu Diyatmika** (Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Lingjun Xue, Jinn P. Chu

Thin film metallic glass as a diffusion barrier for flexible CIGS solar cell on stainless steel substrate: A feasibility study

**Solar energy conversion**

s06-012

**Yen-Jhih Chen** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei City, Taiwan)

Fabrication of Ti doping Hematite Nanotubes Arrays Photoanode *via* Anodic Electrodeposition for Solar Water Splitting

s06-013

**Ramona Gutkowski** (Analytical Chemistry - Center of Electrochemical Science, Ruhr-Universität Bochum, Bochum, Germany), Kirill Sliozberg, Wolfgang Schuhmann

Improvement of the photoelectrocatalytic performance of BiVO<sub>4</sub> by metal doping and co-catalyst decoration using an optical scanning droplet cell

s06-014

**Tsung-Yeh Ho** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei City, Taiwan)

The Study of Carrier Transport/Transfer Mechanism inside CZTS/MS(M=Zn, Cd, Cu)/TiO<sub>2</sub> Nanorods for Solar Water Splitting

s06-015

**Moon-Sung Kang** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Hye-Rin Kim

Performance Enhancement of Perovskite-based Solar Cells with TiO<sub>2</sub> Scaffold by Optimizing Electron-Hole Transport

s06-016

**Jan Macak** (Center of Materials and Nanotechnologies, University of Pardubice, Pardubice, Czech Republic), Milos Krbal, Filip Bures

Hybrid Photoelectrochemical Systems Based on Self-Organized TiO<sub>2</sub> Nanotubes and Novel Chromophores

s06-017

**Wu Zhi** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China), Changjian Lin

Bi<sub>2</sub>S<sub>3</sub> Nanoparticle Modified TiO<sub>2</sub> Nanotube Arrays for High Efficiency of Photoelectrochemical Hydrogen Production

## Symposium 7: Electrodeposition - The Frontier Approach in Material Science and Nanofabrication

### Additives

s07-001

**Satoru Watanabe** (Faculty of Science and Technology, Tokyo University of Science, Noda, Japan), Isao Shitanda, Yoshinao Hoshi, Tatsuo Aikawa, Masayuki Itagaki

Intelligent Self-lubricant Composite Nickel Coating based on Phase Transition of Polystyrene and Polymethyl Methacrylate Particles

### Alloy deposition

s07-002

**Mao-Chun Hung** (Chemical Engineering, National Chung Hsing University, Taichung, Taiwan), Po-Fan Chan, Wei-Ping Dow, Hsiao-Yen Lee, Yi-Sheng Lin, Ping-Feng Yang

Effect of Plating Additives on Microstructure and Properties of Electrodeposited Ni-Fe Alloy

s07-003

**Sho Kawamura** (Department of Applied Material and Life Science, Graduate School of Engineering, Kanto Gakuin University, Yokohama-shi, Japan), Nobuaki Watanabe, Ichiro Koiwa

Pulse Electroplating of Cu-Mo Alloy @Film @Using Disodium Molybdate

s07-004

**Tomio Nagayama** (Surface Finishing Technology Lab., Kyoto Municipal Inst. of Industrial Technology and Culture, Kyoto, Japan), Takayo Yamamoto, Toshihiro Nakamura

Mechanical properties of electrodeposited Fe-Ni alloys in the Invar composition range

s07-005

**Toshihiro Nakamura** (Surface Finishing Technology Lab., Kyoto Municipal Institute of Industrial Tech. and Culture, Kyoto, Japan), Takayo Yamamoto, Tomio Nagayama

Contact Resistance of Thin Gold Overlay on Cu-Sn Alloy Electrodeposits with Various Compositions

s07-006

**Yu-Sheng Wang** (Department of Medicinal and Applied Chemistry, Kaohsiung Medical University, Kaohsiung, Taiwan)

Voltammetric Study and Electrodeposition of Zinc in N-butyl-N-methylpyrrolidinium Bis(trifluoromethanesulfonyl)imide Room Temperature Ionic Liquid

s07-007

**Takayo Yamamoto** (Surface Finishing Technology Lab., Kyoto Municipal Institute of Industrial Tech. and Culture, Kyoto, Japan), Tomio Nagayama, Toshihiro Nakamura

Fabrication of the three-dimensional micro structure by Fe-Ni alloy electroforming process -Effect of saccharin concentration-

s07-008

**Sachio Yoshihara** (Department of Material and Environmental Chemistry, Utsunomiya University, Utsunomiya, Japan), Wataru Oikawa, Yoshifusa Ishikawa, Kazuyoshi Suzuki, Daisuke Suzuki

Application of Amorphous Alloy Plating to Various Industrial Fields

### Bi-polar electrodeposition

s07-009

**Shih-I. Wen** (Chemical Engineering, National Chung Hsing University, Taichung, Taiwan), Wei-Ping Dow

Using Copolymers as Suppressors in a Copper Plating Bath for Through-Hole Filling

### Electroless deposition

s07-010

**Chih-I. Hsu** (School of Defense Science, National Defense University, Taoyuan, Taiwan), Wang Gao-Liang, Ger Ming-Der, Hou Kung-Hsu

Properties of electroless Ni-P/BN(h) composite coatings at elevated temperatures

s07-011

**Xinyu Liu** (Chemical and Biomolecular Engineering, Case Western Reserve University, Cleveland, USA), Xun Zhan, Frank Ernst, Rohan Akolkar, Werner Richtering

Electroless Deposition of Amorphous Nickel-Tungsten-Phosphorus Alloys with Superior Resistance to Crystallization

s07-012

**Tzu-Hsuan Tsai** (Department of Materials and Mineral Resources Engineering, National Taipei University of Technology, Taipei, Taiwan), Yu-Pei Shih

Recovery of Nanosilver from Si-Wafer Manufacturing Wastes

s07-013

**Yaping Zhao** (College of Chemistry, Chemical Engineering & Biotechnology, Donghua University, Shanghai, China), Hong Zhao, Caihong Liu, Bingzheng Song, Zaisheng Cai

Electromagnetic Shielding Polyamide Fabrics prepared by Electroless Ni Plating with Chitosan-Nickel Complexes Activation

## Nucleation

s07-014

**Atsushi Iwanaga** (Elemental Technology R&D, Y Lab, Furukawa, Japan), Hisayoshi Matsushima, Satoshi Miyazawa, Shinichi Nagano

Numerical Simulation of Current Density Distribution between Vertical Cu Electrode

s07-015

**Peter Keech** (Nuclear Waste Management Organization, Toronto, Canada), Peter Lin, Neil Mahalanobis

Electrodeposited Copper Coatings for Used Fuel Containers

s07-016

**Kai Nakamura** (Materials Science and Engineering, Kyoto University, Kyoto, Japan), Atsushi Kitada, Kazuhiro Fukami, Kuniaki Murase

Characterization of  $\text{AlCl}_3$ /Diglyme Solution for Aluminum Electrodeposition

s07-017

**Jon Ustarroz** (Electrochemical and Surface Engineering (SURF), Vrije Universiteit Brussel, Brussels, Belgium), El Amine Mernissi Cherigui, Pieter Bouckennooge, Kadir Sentosun, Mesfin Haile Mammé, Herman Terryn, Sara Bals, Annick Hubin

Electrodeposition of Nickel Nanostructures from Deep Eutectic Solvents: New Insights into Nucleation and Growth Mechanisms

## Thin films

s07-018

**Chun-Yi Chen** (Precision and Intelligence Laboratory, Tokyo Institute of Technology, Yokohama, Japan), Xun Luo, Tso-Fu Mark Chang, Masato Sone

Effect of Supercritical Carbon Dioxide on Crystal Structure of Electrodeposited Cobalt Films

s07-019

**Caimei Fan** (College of Chemistry and Chemical Engineering, Taiyuan University of Technology, Taiyuan, China), Yingyuan Hu, Rui Li, Xiaoming Mao

One-step Synthesis of Porous BiOBr Film from Bi Plate *Via* Electrochemical Method

s07-020

**Yuya Ito** (Department of Applied Material and Life Science, Graduate School of Engineering, Kanto Gakuin University, Yokohama-shi, Japan), Ichiro Koiwa, Nobuaki Watanabe

Control of Crystal Orientation of Electrodeposited Aluminum Films from Bath Using  $\text{DMSO}_2$  as a Solvent

s07-021

**Ichiro Koiwa** (Department of Applied Chemistry, College of Science and Engineering, Kanto Gakuin University, Yokohama-shi, Japan), Nobuaki Watanabe, Akihiro Yamamoto, Kenta Chokki, Kazuhiro Yabe

$\text{Zn-AlO}_x(\text{OH})_y$  Composite Films Prepared from Non-Suspended Solution by Electrochemical Technique

s07-022

**Song-Zhu Kure-Chu** (Department of Chemistry and Bioengineering, Iwate University, Morioka, Japan), Toru Ogasawara, Hitoshi Yashiro, Kuniaki Sasaki

Thermal Stability and Sulfidizing Resistance of High Reflective Sn/Ag<sub>3</sub>Sn-based Films Electrodeposited on Cu

s07-023

**Chia Wen Liao** (Chung-Cheng Institute of Technology, National Defense University, Taoyuan, Taiwan), Kung Hsu Hou, Ming-Der Ger

Characterization of the Cr-C-Si<sub>3</sub>N<sub>4</sub> Composite Coatings Electroplated from a Trivalent Chromium Bath

s07-024

**Cheng-Lan Lin** (Department of Chemical and Materials Engineering, Tamkang University, New Taipei City, Taiwan), Kuen-Yi Ding

Electrostatic Field-Assisted Direct Potentiostatic and Pulse-Potential Electrodeposition of Prussian Blue Films

s07-025

**Kuniaki Murase** (Department of Materials Science and Engineering, Kyoto University, Kyoto, Japan), Yusuke Seki, Tsutomu Shinagawa, Atsushi Kitada, Kazuhiro Fukami

Electrodeposition of Cu<sub>2</sub>O from Aqueous Lactate Solutions - Studies on Copper(II) Complexes in Alkaline Deposition Baths

s07-026

**Yusuke Okamura** (IMRAM, Tohoku University, Sendai, Japan), Itaru Honma

Electrodeposition of mono-layer graphene from carboxylic acid under hydrothermal condition

s07-027

**Liza Rassaei** (Chemical Engineering, Delft University of Technology, Delft, Netherlands), Hanan Al-Kutubi, Jorge Gascon, Ernst Sudholter, Hamid Reza Zafarani, Alla Dikhtiarenko

Synthesis of ZIF-8 metal organic framework thin film on ZnO nanorods

s07-028

**Mei-Jywan Syu** (Chemical Engineering, National Cheng Kung University, Tainan, Taiwan), Yan-Di Tseng

Amperometric Detection of Bilirubin *via* A Room-Temperature Ionic Liquid-Imprinted Polymer Composite Electrode

s07-029

**Takuya Tokuda** (Graduate School of Advanced Integrated Science, Chiba University, Chiba-shi, Inage-ku, Yayoi-cho, Japan), Dan Takamura, Katsuyoshi Hoshino

Electrochemical preparation of novel metal-like lustrous films

s07-030

**Pu-Wei Wu** (Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan), Po-Chun Chen, Chia-Yun Hsu, Shih-Cheng Chou, Aniruddha Joi, Yezdi Dordi, Jyh-Fu Lee

Electrodeposition of CuMn thin film from a nonaqueous electrolyte

s07-031

**Yu-Beom Yeon** (Department of Advanced Materials Chemistry, Korea University, Sejong Special Self-Governing City, Korea), Viswanathan Saji

Electrodeposition of Copper, Indium, Gallium and Selenium on Molybdenum Investigated by Voltammetry, X-Ray Diffraction, and Scanning Electron Microscopy/Energy Dispersive Spectroscopy

s07-032

**Claudio Zafferoni** (Department of Chemistry Ugo Schiff, Florence, Italy), Serena Cinotti, Francesco Di Benedetto, Andrea Giaccherini, Giordano Montegrossi, Annalisa Guerri, Francesco Carlà, Roberto Felici, Massimo Innocenti

Synthesis and characterization of metal sulfides for solar devices

## Symposium 8: Corrosion and Passivity

### Corrosion

s08-001

**Silviu Drob** (Electrochemistry and Corrosion, Institute of Physical Chemistry Ilie Murgulescu, Bucuresti, Romania), Cora Vasilescu, Jose Maria Calderon Moreno, Petre Osiceanu

A New Dental Alloy with Improved Properties: Its Corrosion Resistance in Various Conditions Simulating Oral Cavity Environment

s08-002

**I-Wen Huang** (Materials Science and Engineering, The Ohio State University, Columbus, USA), Rudolph Buchheit

Assessing and Predicting Concurrent Uniform Corrosion of Aluminum Alloys as a Function of pH, Temperature, Time, and [Cl<sup>-</sup>]

s08-003

**Jia-Lin Jhan** (Department of Chemical Engineering and Materials Science, Yuan Ze University, Taoyang, Taiwan), Leo Chau-Kuang Liao

Corrosion of Indium Tin Oxide Films in SiO<sub>2</sub> Solutions

s08-004

**Katsutoshi Nakayama** (Graduate School of Chemical Sciences and Engineering, Hokkaido University, Sapporo, Japan), Etsushi Tsuji, Yoshitaka Aoki

Fabrication of super-liquid-repellent aluminum mesh with chemical etching/anodizing

s08-005

**Mikhail Pletnev** (Innovative, Izevsk State Technical University, Izhevsk, Russia)

Comparative analysis of the anodic dissolution of iron at low and high over potentials

s08-006

**Britta Schafstaller** (BTT-SF, Atotech Deutschland, Berlin, Germany), Mathias Wuensche, Sebastian Weissbrod, Grigory Vazhenin, Constanze Donner

Au Immersion on mid NiP Substrates – Balance between NiP Dissolution and Au-Adhesion properties

s08-007

**Maria Stepanova** (Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway), Otto Lunder, Jan Halvor Nordlien, Kemal Nisancioglu

Corrosion resistance of zinc diffusion layers on aluminium

### *In-situ* corrosion measurements

s08-008

**Thangaraj Balusamy** (Materials Recycling Design Group, NIMS, Tsukuba, Japan)

Evaluation of the corrosion behaviour of epoxy coated carbon steel at the damaged zone in saturated Ca(OH)<sub>2</sub> with varying concentration of chloride ions by localized electrochemical impedance spectroscopy

s08-009

**Lin Niu** (Department of Chemistry, Shandong University, Jinan, China), Xiaoping Han, Yu Liu, Weiwei Zhang, Rui Ma, Shuai Li, Tong Li

Local Electrochemical Study on the Effect of Residual Stresses on Localized Corrosion Susceptibility of Type 316 Stainless Steels

s08-010

**Bo Zhao** (Research and Development Center, China Special Equipment Inspection And Research Institute, Beijing, China), Zhiyong Liu, Cuiwei Du, Xiaogang Li, Binan Shou, Tong Xu

Influence of Crevice Thickness to Corrosion Behavior of API X80 Steel under Disbonded Coating in Acid Soil Environment

**Passive films**

s08-011

**Ahmed Galal** (Chemistry, Kuwait University, Kuwait, Kuwait), Mohammad BinSabt, Kamal Shalabi, Faizah Al-Kharafi

Protection of Al93Mg7 Alloy against Corrosion in NaCl Containing Solutions Using Silane and Silane-Graphene Films

s08-012

**Shun-Yi Jian** (Department of Materials Science and Engineering, National Taiwan University, Taipei, Taiwan), Yueh-Lien Lee, Chao-Sung Lin

Electrochemical Corrosion Behavior of Permanganate Conversion Coating on AZ31B Magnesium Alloys - Long Term Evaluation by EIS

s08-013

**Chengqiang Ren** (School of Materials Science and Engineering, Southwest Petroleum University, Chengdu, China), Ye Peng, Jiameng Li, Jingsi Hu, Bo Liu, Li Liu

Electrochemical Investigation on Passivation Characteristic of P110 Steel in Alkaline Solution

s08-014

**Emmanuel Rocca** (Institut Jean Lamour UMR CNRS, Université de Lorraine, Vandoeuvre Les Nancy, France), Joffrey Tardelli

Electrochemical properties of  $\eta$ -MgZn<sub>2</sub> phase in sulfuric acid : anodizing behavior at high potential

s08-015

**Cora Vasilescu** (Electrochemistry and Corrosion, Institute of Physical Chemistry Ilie Murgulescu, Bucuresti, Romania), Silviu Drob, Silviu Preda, Jose Maria Calderon Moreno, Petre Osiceanu

Passive Film Characterization on New Ternary Ti-Ta-Zr Alloy Surface

s08-016

**Delphine Veys-Renaux** (Institut Jean Lamour, Université de Lorraine, CNRS, Vandoeuvre les Nancy, France), Emmanuel Rocca, Khadoudj Guessoum

Zinc anodizing at high voltage in alkaline media

---

## Symposium 9: Electrocatalytic Materials

---

**Electrocatalytic materials**

s09-001

**Nathalia Abe Santos** (Instituto de Química de São Carlos, Universidade de São Paulo, São Carlos, Brazil), Patricia Gon Corradini, Joelma Perez

Study of ethanol electro-oxidation on PtNd/C and PtSnNd/C: stability test and FTIR

s09-002

**Ludwig Asen** (Fakultät für Chemie, Technische Universität München, Garching, Germany), Ehab Mostafa, Wenbo Ju, Sladjana Martens, Ulrich Heiz, Ulrich Stimming, Oliver Schneider

Electrodeposition of Novel Materials as ORR Catalysts for MEAs

s09-003

**Helmut Baltruschat** (Chemistry, University of Bonn, Bonn, Germany), Hatem M.A. Amin, Sevda Ayata

Synergistic Electrocatalytic Effects on Oxides + Ag - Electrodes for Oxygen Reduction and Evolution

s09-004

**Ausra Baradoke** (Department of Nanoengineering, Center for Physical Sciences and Technology, Vilnius, Lithuania), Isabel Pastoriza-Santos, Elisa Gonzalez-Romero

Ruthenium Nanocomposites for Electrochemical Detection: Design and Modification of Graphene Electrodes for Biosensors

s09-005

**Stefan Barwe** (Analytical Chemistry – Center for Electrochemical Science, Ruhr-Universität Bochum, Bochum, Germany), Stefan Klink, Wolfgang Schuhmann

A poly(benzoxazine) as binder matrix for OER catalysts derived from Prussian blue analogue precursors

s09-006

**Jiajin Bi** (Graduate School of Engineering, Yokohama National University, Yokohama, Japan), Koichi Matsuzawa, Yuji Kohno, Shigenori Mitsushima

Catalytic Activity and Durability for Oxygen Evolution on LaNiO<sub>3</sub>/Ni for Alkaline Water Electrolysis under Potential Cycling

s09-007

**Stanko Brankovic** (Electrical and Computer Engineering, University of Houston, Houston, USA), Qiuyi Yuan, Hieu Doan, Lars Grabow

Structure vs. Properties Relation in Novel RuPt Core-Edge Catalyst Nanoclusters

s09-008

**Cheng-Chuan Chen** (Department of Bio-Industrial Mechatronics Engineering, National Taiwan University, Taipei City, Taiwan)

Pd-based bimetallic nanocatalysts for alkaline glucose electrooxidation and fuel cells application

s09-009

**Qiaoli Chen** (Department of Chemistry, Xiamen University, Xiamen, China), Zhaoxiong Xie

Synthesis of Excavated Trioctahedral Au<sup>+</sup>CPd Alloy Nanocrystals with Tunable Composition for Electro-Oxidation of Ethanol

s09-010

**Yuan Chen** (School of Chemical and Biomedical Engineering, Nanyang Technological University, Singapore, Singapore)

Bacteria Derived Carbon as High-Performance Electrocatalysts

s09-011

**Kui Cheng** (College of Material Science and Chemical Engineering, Harbin Engineering University, Harbin, China)

Design and fabrication Co<sub>3</sub>O<sub>4</sub>-based electrode and its application for H<sub>2</sub>O<sub>2</sub> electroreduction

s09-012

**Nan-Kuang Chou** (Department of Chemical and Materials Engineering, National Kaohsiung University of Applied Sciences, Kaohsiung City, Taiwan), Meng-Shan Hsieh, Chien-Liang Lee

Different-sized truncated Pd nanocubes for glucose electrooxidation

s09-013

**Martín Dávila** (Fisicoquímica, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico)

Electrochemical Oxidation of Dibenzothiophene and Dibenzothiophene Sulphone

s09-014

**Ali Ehsani** (Chemistry, Qom University, Qom, Iran)

Physioelectrochemical properties and catalytic activity of green synthesized metal oxide nanoparticles and conductive polymer composite film

s09-015

**Makoto Eto** (Graduate School of Engineering, Oita University, Oita, Japan), Taro Kinumoto, Kohei Ono, Tomoki Tsumura, Masahiro Toyoda

Oxygen Evolution Reaction Behavior of Vapor Grown Carbon Fiber and the Loading Effect of LaMnO<sub>3</sub> in KOH Aqueous Solution

s09-016

**Miao-Syuan Fan** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Chuan-Pei Lee, Chun-Ting Li, Yi-June Huang, R. Vittal, Kuo-Chuan Ho

Molybdenum Disulfide/Nitrogen-Doped Graphene Composite as an Electrocatalytic Material for Dye-Sensitized Solar Cells

s09-017

**Lucia Fernandez Macia** (Electrochemical and Surface Engineering Group, Vrije Universiteit Brussel, Brussels, Belgium), Bart Geboes, Jon Ustarroz, Laurens Stevaert, Tom Breugelmans, Annick Hubin

A Reliable and Quantitative Characterization of Electrocatalysts Towards the Oxygen Reduction Reaction from LSV/RDE Experiments

s09-018

**Kobra Ghobadi** (Chemistry, Yazd University, Yazd, Iran), Hamid Reza Zare, Hossein Khoshro, Alireza Gorji, Abbas Ali Jafari

Electrocatalytic Synthesis of Cinnamic Acid by Reaction of Electrocatalytic Activated CO<sub>2</sub> with Phenylacetylene

s09-019

**Kristoffer Hedenstedt** (Chemistry and Molecular Biology, University of Gothenburg, Gothenburg, Sweden), Elisabet Ahlberg, Nina Simic, Mats Wildlock

Electrochemical Investigation of Water Reduction on Goethite, Lepidocrocite and Mild Steel in Slightly Alkaline Electrolyte

s09-020

**Takahiro Hirai** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Tian Zhang, Masatsugu Morimitsu

Composition, Structure, and Kinetics of RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub>/Ti Anode for Oxygen Evolution in H<sub>2</sub>SO<sub>4</sub> Solutions

s09-021

**Huin-Ning Huang** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Wei-Hung Chiang

Synthesis of Metal Nanoparticle/Graphene Nanocomposites using Atmospheric-Pressure-Microplasma-Assisted Electrochemistry

s09-022

**Yi-June Huang** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Chuan-Pei Lee, Miao-Syuan Fan, Chun-Ting Lee, R. Vittal, Kuo-Chuan Ho

A Pt-Free Counter Electrode based on Novel Cobalt Diselenide Architectures for Dye-Sensitized Solar Cells

s09-023

**Eunkyoung Hwang** (School of Integrative Engineering, Chung-Ang University, Seoul, Korea), Soo-Kil Kim, Sung Hoon Hong, Jihui Choi, Jin Yeung Kim, Hoyoung Kim

Electrocatalysts for CO<sub>2</sub>-C<sub>1</sub> Fuel Inter-conversion

s09-024

**Suyeon Hyun** (Energy Systems Engineering, Daegu Gyeongbuk Institute of Science & Technology (DGIST), Daegu, Korea), Vignesh Ahilan

Porous Co<sub>3</sub>V<sub>2</sub>O<sub>8</sub> Nanostructures as Promising Electrocatalyst for Oxygen Evolution Reaction in Alkaline Medium

s09-025

**Yukiko Ishimura** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Kenji Kawaguchi, Masatsugu Morimitsu

Oxygen Reduction on RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> Mixed Oxide Catalyst in Alkaline Solution

s09-027

**Hwakyeung Jeong** (Chemistry, Chungbuk National University, Cheongju, Korea)

Electrodeposition of Nanoflake Pd Structures: Structure-Dependent Wettability and SERS Activity

s09-028

**Abdel-Nasser Kawde** (Chemistry, King Fahd University of Petroleum and Minerals, Dhahran, Saudi Arabia)

Successful Strategies to Overcome the Carbon Electrodes Surfaces Fouling of Phenols

s09-029

**Jin Yeong Kim** (School of Integrative Engineering, Chung-Ang University, Seoul, Korea), Jihui Choi, Sung Hoon Hong, Hoyoung Kim, Eunkyoung Hwang, Soo-Kil Kim

Ru/M Bi-layered Oxide Catalysts for Oxygen Evolution Reaction (OER) in Acidic Water Splitting

s09-030

**Seulki Kim** (Department of Applied Chemistry, Konkuk University, Chungju, Korea), Changhyun Lee, Noseung Myung

Synthesis of Pt-CuO Composite *via* Electrodeposition Followed by Galvanic Replacement-Heat Treatment and Its Application to Non-Enzymatic Glucose Sensor

s09-031

**Joosun Kim** (High-Temperature Energy Materials Research Center, Korea Institute of Science and Technology, Seoul, Korea), Donghyun Bae, Miyoung Yoon, Eunseok Kwon, Seunghwan Lee, Jooho Moon, Hyunjung Shin

Catalytic Performance and Characterization of Iron Oxide-Based Composite Catalyst for Reduction of CO<sub>2</sub>

s09-032

**Shuhei Kimura** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Kenji Kawaguchi, Masatsugu Morimitsu

Effects of Precursor Solution on Morphology and Catalytic Activity of RuO<sub>2</sub>-based Ti anode for Oxygen Evolution

s09-033

**Anthony Kucernak** (Chemistry, Imperial College London, London, United Kingdom)

New palladium phosphide catalysts for fuel cell relevant reactions

s09-034

**Kousuke Kumamoto** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Tian Zhang, Masatsugu Morimitsu

Effects of Composition of Amorphous IrO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> Coatings on Oxygen Evolution in Alkaline Solutions

s09-035

**Dong Wook Lee** (Department of Chemical and Biomolecular Engineering, Yonsei University, Seoul, Korea), Woong Hee Lee, Hansung Kim

Enhancement on ORR Activity of N-Doped Carbon Catalysts Derived from Melamine Based Polymer

s09-036

**Seunghwa Lee** (School of Environmental Science and Engineering, Gwangju Institute of Science and Technology, Gwangju, Korea), Jaeyoung Lee

On The Role of Cl<sup>-</sup> : Synergistic Effects with Cu<sub>2</sub>O for The Electroreduction of CO<sub>2</sub> to Multi-Carbon Fuels

s09-037

**Andreas Lesch** (Laboratory of Physical and Analytical Electrochemistry, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland), Victor Costa Bassetto, Hubert Girault

Preparing electrocatalysts for energy conversion by inkjet printing and photonic curing in one fabrication process

s09-038

**Philipp Lettenmeier** (Institute of Engineering Thermodynamics, German Aerospace Center, Stuttgart, Germany), Schwan Hosseiny, Li Wang, Aldo Saul Gago, Kaspar Andreas Friedrich

Synthesis and Characterization of Highly Active Ir Nanoparticles for Oxygen Evolution Reaction in Acid Media

s09-039

**Xiaoheng Liu** (College of Chemical Engineering, Nanjing University of Science and Technology, Nanjing, China), Wei Chen

One-step Hydrothermal Route to Fabricate Novel ZnIn<sub>2</sub>S<sub>4</sub>/g-C<sub>3</sub>N<sub>4</sub> Heterojunction Photocatalysts with Highly-efficient Visible Light Response

s09-040

Cancelled

s09-041

**Nai-Chang Lo** (Chemistry, National Cheng Kung University, Tainan, Taiwan)

Electrochemical Formation of Cu Nanoparticles in Tributyl-Methylammonium bis((trifluoromethyl)sulfonyl)imide Room-Temperature Ionic Liquid

s09-042

**Juan Manriquez** (Department of Research, Cideteq, Pedro Escobedo, Mexico)

Orange II mineralization on C-modified nanoparticulate TiO<sub>2</sub> cathodes able for producing OH• radicals through the O<sub>2</sub> reduction which is simultaneously generated on a grade 2 Ti anode *via* the H<sub>2</sub>O oxidation

s09-043

**Yu-Xiang Mao** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Chun-Jern Pan, Men-Che Tsai, Wei-Nien Su, Bing-Joe Hwang

Ni-based bimetallic nanoparticles as active and durable catalysts towards hydrogen oxidation reaction

s09-044

**Jun Maruyama** (Environmental Technology Research Division, Osaka Municipal Technical Research Institute, Osaka, Japan), Takahiro Hasegawa, Satoshi Iwasaki, Tomoko Fukuhara, Yuki Orikasa, Yoshiharu Uchimoto

Carbonaceous Thin Film Coating with Fe–N<sub>4</sub> Site for Enhancement of Dioxovanadium Ion Reduction

s09-045

**Kenji Matsumae** (Engineering, Yokohama National University, Yokohama, Japan), Kohei Nagai, Yuji Kohno, Koichi Matsuzawa, Shigenori Mitsushima

Degradation of IrO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> / Ti anode with toluene contamination

s09-046

**Hisayoshi Matsushima** (Faculty of Engineering, Hokkaido University, Sapporo, Japan), Shota Shibuya, Ryota Ogawa, Mikito Ueda

Kinetic Isotope Effect on Hydrogen Evolution and Oxidation Reaction

s09-047

**Eugenijus Norkus** (Department of Catalysis, Center for Physical Sciences and Technology, Vilnius, Lithuania), Jane Jaciauskiene, Kestutis Prusinskas, Irena Stalnioniene, Loreta Tamasauskaite-Tamasiunaite, Dordi Yezdi, Aniruddha Joi

The Use of Environmentally-Friendly Natural Polyols as Cu(II) Ligands in Electroless Copper Plating Processes

s09-048

**Eugenijus Norkus** (Department of Catalysis, Center for Physical Sciences and Technology, Vilnius, Lithuania), Loreta Tamasauskaite-Tamasiunaite, Zita Sukackiene, Aldona Balciunaite, Algirdas Selskis

Gold Nanoparticles Modified Cobalt-Boron-Copper and Cobalt-Boron-Tungsten-Copper as Electrocatalysts for Borohydride Oxidation

s09-049

**Lidia Jagoda Opuchlik** (Faculty of Chemistry, University of Warsaw, Warsaw, Poland), Renata Bilewicz

Anisotropic gold nanoplates – characterization and application in catalysis

s09-050

**Ali Riza Ozkaya** (Chemistry Department, Marmara University, Istanbul, Turkey), Zuhail Yazar, Mehmet Piskin, Zafer Odabas

Redox properties and electrocatalytic oxygen reducing performances of various novel metal phthalocyanines

s09-051

**Chien-Yeh Pan** (Department of Applied Chemistry, National Chiao Tung University, Taipei, Taiwan), Chia-Kan Hao, Chi-Shen Lee

Metal-doped Pyrochlore as Novel Anode Material for Intermediate Solid Oxide Fuel Cell

s09-052

**Jun Peng** (Faculty of Chemistry, Northeast Normal University, Key Laboratory of Polyoxometalate Science of Ministry of Education, Changchun, China)

Assembly of hybrids based on Keggin POMs and Co-tris(imidazolyl) complexes with bifunctional electrocatalytic activities

s09-053

**Morihiro Saito** (Department of Applied Chemistry, Tokyo University of Agriculture and Technology, Koganei-shi, Japan), Shinpei Kosaka, Chiaki Tsukada, Hiroshi Suzuki, Hidenobu Shiroishi, Yumi Tanaka, Shiro Seki

New Air Electrode Catalysts Based on Mn Oxide Nanosheet/Nanocarbon Composite Materials for Li Air Batteries

s09-054

**Yanyan Song** (College of Science, Northeastern University, Shenyang, China), Zhida Gao, Patrik Schmuki  
Carbon Cladded TiO<sub>2</sub> Nanotubes Enabling Highly Defined RuO<sub>2</sub> Decoration for Efficient Supercapacitor Performance

s09-055

**Yung-Tao Sung** (Chemical Engineering, National Taipei University of Technology, Taipei, Taiwan), Jun-Ming Chiu, Chao-Chi Tu  
Improved Visible-light Photoelectrochemical Water Oxidation using Titanium Dioxide /Antimony Trisulfide Heterojunction Structure

s09-056

**Hogiartha Sutiono** (Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Ching-Hsiang Chen, Wei-Nien Su, Liang-Yih Chen, Bing-Joe Hwang  
A Shortcut: Core (Rutile) – Shell (Anatase) Nanorods for Highly Efficient Solar Water-Splitter

s09-057

**Takuma Suzuki** (Department of Pure and Applied Chemistry, Tokyo University of Science, Noda, Japan), Yoshinao Hoshi, Isao Shitanda, Masayuki Itagaki  
Motion control of TiO<sub>2</sub>/Pt/Au nanomotor by UV light irradiation

s09-058

**Loreta Tamasauskaite-Tamasiunaite** (Department of Catalysis, Center for Physical Sciences and Technology, Vilnius, Lithuania), Gilius Kisielius, Teofilis Kilmonis, Aldona Balciunaite, Ina Stankeviciene, Aldona Jagminiene, Agne Matuseviciute, Eugenijus Norkus  
Preparation of Graphene Supported PtCoMo by Electroless Deposition

s09-059

**Dong-Ying Tzou** (Chemical Engineering and Materials Science, Yuan Ze University, Chung-Li, Taiwan), Chien-Te Hsieh, Yu-Fu Chen, Jen-Hao Hsueh  
Graphene and Carbon Nanotube Composites as Electrode Materials for Electrochemical Capacitors in Organic Electrolyte

s09-060

**Dong-Ying Tzou** (Department of Chemical Engineering and Materials Science, Yuan Ze University, Chung-Li, Taiwan)  
Synthesis of MnO<sub>2</sub>/Carbon Composites as Electrode Materials for Supercapacitors

s09-061

**Yusuke Ujino** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Kenji Kawaguchi, Masatsugu Morimitsu  
Formation and Electrochemical Behaviors of RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> Coating on Pb Substrate for Oxygen Evolution

s09-062

**Shan-Yu Wang** (Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Yan-Sheng Li, Wei-Hung Chiang  
Controllable Synthesis of Metal Nanoparticle/Graphene Nanoribbon Composites

s09-063

**Chen-Hao Wang** (Department of Materials Science and Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan), Yu-Chen Shih, Yu-Chung Chang, Ning-Yih Hsu, Yi-Sin Chou  
Functionalization of Carbon Felt as Catalytic Material for Vanadium Redox Flow Battery

s09-064

**Yu-Ching Weng** (Department of Chemical Engineering, Feng Chia University, Taichung, Taiwan), Wei-Fen Xiong  
Screening of Ru-based Electrocatalysts for Oxygen Reduction by Scanning Electrochemical Microscopy

s09-065

**Lindsay Wilson** (Chemistry, University of the Western Cape, Cape Town, South Africa), Candice Rassie, Priscilla Baker, Emmanuel Iwuoha  
Electrochemical Responses of Transglutaminase Immunosensor Developed on a Polypyrrole-Cobalt (II) Salicyladiimine Dendritic Composite Material

s09-066

**Ching Chou Wu** (Department of Bio-Industrial Mechatronics Engineering, National Chung Hsing University, Taichung, Taiwan), Ming Yuan Lee

Fabrication of nanostructured copper phosphate electrodes for the detection of  $\alpha$ -amino acids

s09-067

**Yi-Shan Wu** (Department of Chemical and Materials Engineering, National Kaohsiung University of Applied Sciences, Kaohsiung City, Taiwan), Chien-Liang Lee

Electrophoretic deposition of graphene sheets on porous nickel foam as effective catalysts for oxygen evolution reaction and hydrogen peroxide sensor

s09-068

**Ke Ye** (College of Materials Science and Chemical Engineering, Harbin Engineering University, Harbin, China), Dianxue Cao, Hongyu Zhang, Long Yang, Xin Wang, Kui Cheng

Three-dimensional Nickel Film Electrodeposited on Porous Carbon Sponge: High Catalytic Performance and Low-cost Anode for Urea Electro-oxidation in Alkaline Medium

s09-069

**Hiromu Yoshida** (Department of Material Chemistry, Graduate School of Engineering, Kyoto University, Kyoto, Japan)

Fundamental Studies on Electrochemical Oxidative Properties of a Gold Nanoparticle-Attached Palladium Electrode

s09-070

**Sawaguchi Yuki** (Science and Engineering, Yokohama National University, Yokohama, Japan), Yasutomo Takakuwa, Kensaku Nagasawa, Yuji Kohno, Koichi Matsuzawa, Shigenori Mitsushima

Polarization for a toluene hydrogenation electrolyzer with various concentration of toluene feed

s09-071

**Xinsheng Zhang** (Department of Chemical Reaction Engineering, East China University of Science and Technology, Shanghai, China), Rensheng Zhong, Dongfang Niu

The effect of surface functional groups of carbon nanofiber on oxygen reduction reaction

s09-072

**Ming Zhou** (Chemistry, The University of Hong Kong, Hong Kong, China), Kwong-Yu Chan

RuO<sub>2</sub> nanoparticles loaded well-defined iron-nitrogen doped mesoporous core-shell carbon spheres as an effective cathode for rechargeable lithium-oxygen battery

---

## Symposium 10: Electrochemical Technology: New Challenges for a More Competitive Economy

---

### Electrochemical technology

s10-001

**Henry Bergmann** (FB 6 & 7, Anhalt University, Köthen, Anh., Germany)

On the continuity of chlorine production during electrochemical water disinfection

s10-002

**Roel Bisselink** (Water Treatment, TNO, Zeist, Netherlands), Mathias Panjer

Indium recovery from secondary sources by electrowinning

s10-003

**Roel Bisselink** (Water Treatment, TNO, Zeist, Netherlands), Lourens Feenstra

Electrochemical synthesis of hydrogen peroxide coupled with UV-C for the oxidation of endocrine disruptor compounds

s10-004

**Erika Bustos** (Science, Centro de Investigación y Desarrollo Tecnológico en Electroq, Querétaro, Mexico), Maribel Pérez-Corona, José Alberto García, Gabor Taller, Dorothy Polgár, Zsuzsana Plank

The Cone Penetration Test and 2D Imaging Resistivity as Tools to Simulate the Distribution of Hydrocarbon in Soil

s10-005

**Miao-Syuan Fan** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Ling-Yu Chang, Chuan-Pei Lee, R. Vittal, Jiang-Jen Lin, Kuo-Chuan Ho

Synthesis of a Novel Polymeric Ionic Liquid for Electrochromic Device Application

s10-006

**Ali Farhat** (Advanced Water Management Centre, University of Queensland, Brisbane, Australia), Stephan Tait, Jurg Keller, Jelena Radjenovic

Removal of Persistent Organic Contaminants by Electrochemically Activated Sulfate

s10-007

**Carmen Maria Fernandez Marchante** (Chemical Engineering, University of Castilla La Mancha, Ciudad Real, Spain), Manuel Andres Rodrigo, Carolina Risco, Cristina Sáez, Rubén López-Vizcaíno, Pablo Cañizares, Vicente Navarro

Electrokinetic remediation of natural soil polluted with the herbicide 2,4-D

s10-008

**Sergi Garcia-Segura** (Chemistry, Universidade Federal do Rio Grande do Norte, Natal, Brazil), Amison Rick Lopes da Silva, Gustavo Rodrigues de Oliveira, Carlos Alberto Martinez-Huitle

Electrochemical Oxidation of 2-Naphthol on BDD Anodes: Dissolved Oxygen Participation, Mechanism and Theoretical Calculations

s10-009

**Li Guan** (Chemical & Environmental Engineering, The University of Nottingham, Nottingham, United Kingdom), George Zheng Chen

Intact Recovery of Carbon Nanotubes from their Conducting Polymer Composites *via* Selective Fenton-Oxidation

s10-010

**Lianhuan Han** (Department of Chemistry, Xiamen University, Xiamen, China)

A Novel Processing Method and Simulation Based on Confined Etching Layer Technique

s10-011

**Yosuke Imanishi** (Graduate School of Human and Environmental Studies, Kyoto University, Kyoto, Japan), Tatsuma Yahara, Tatsuro Haruki, Yuki Orikasa, Yoshiharu Uchimoto

Development of Intermediate Temperature Fuel Cells using Methylcyclohexane Organic Hydride Fuel

s10-012

**Ye-Jin Jeong** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Chan-Soo Kim, Nam-Jo Jeong, Jin-Soo Park

Effect of Simulated Foulants on Membrane Fouling in Reverse Electrodialysis

s10-013

**Babak Khalaghi** (Department of Materials Science and Engineering, Norwegian University of Science and Technology, Trondheim, Norway)

Supplying of Methane through Porous Carbon Anodes during Aluminium Electrolysis

s10-014

**Jong-Hoon Kim** (Electrical Engineering, Power Electronics Lab, Ajou University, Suwon, Korea), Jung-Nam Lee, Chung-Yul Yoo

Toward Cost Effectiveness of Alkaline Water Electrolysis for Hydrogen Economy

s10-015

**Javier Llanos** (Department of Chemical Engineering, University of Castilla-la Mancha, Ciudad Real, Spain), F. L. Souza, Cristina Sáez, M.V. Lanza, Pablo Cañizares, Manuel Andres Rodrigo

Coupling Wind Turbines and PV Panels to Electrochemical Processes: Treatment of Wastewater and Soil Polluted with Herbicides

s10-016

**Paulo Olivi** (Departamento de Química, FFCLRP, Universidade de São Paulo, Ribeirão Preto, Brazil), Cláudio Castro

Electrochemical oxidation of Disperse Yellow 3 dye using BDD electrodes

s10-017

**Juan Manuel Paz-Garcia** (Division of Solid Mechanics, Lund University, Lund, Sweden), Maria Villen-Guzman, Jose M. Rodriguez-Maroto, Cesar Gomez-Lahoz, Matti Ristinmaa, Stephen Hall

Electrokinetic Remediation of Lead-contaminated Carbonate-rich Soil

s10-018

**Carlos Ponce de Leon** (Faculty of Engineering and the Environment, University of Southampton, Southampton, United Kingdom), I. Ishita, Vanessa M. Vasconcelos, Marcos R.V. Lanza, José L. Nava

Electrochemical degradation of RB-5 dye by anodic oxidation, Electro-Fenton and by combining anodic oxidation-electro-Fenton in a filter-press flow cell

s10-019

**Ricardo Salazar** (Química de los Materiales, Universidad de Santiago de Chile, Santiago, Chile)

Degradation of Industrial Textile Dye Disperse Red BG by electro-oxidation: Role of Anode, pH and Supporting Electrolyte

s10-020

**Onofrio Scialdone** (Dipartimento di Ingegneria Chimica, Gestionale, Informatica, Università degli Studi di Palermo, Palermo, Italy), Alessandro Galia, Simona Sabatino

Electrochemical reduction of carbon dioxide to formic acid at tin cathode in divided and undivided cells: Effect of operating parameters

s10-021

**Kazuya Takeuchi** (Dept of Science of Environment and Mathematical Modeling, Doshisha University, Kyotanabe, Japan), Kenji Kawaguchi, Masatsugu Morimitsu

A Challenge to Synthesize  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$ -based Hybrid Oxide for Oxygen Reduction

s10-022

**Po-Chih Tsai** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan), Bing-Joe Hwang, Wei-Nien Su, Hsin-Fu Deng

Metal Ion Additive Effect on the Morphology of Silicon Etching

s10-023

**Elisama Vieira dos Santos** (Institute of Chemistry, Federal University of Rio Grande do Norte, Natal, Brazil), Cristina Sáez, Pablo Cañizares, Manuel Andres Rodrigo, Carlos Alberto Martinez-Huitle

Extraction Agents for Removing Petroleum from Soil and Application of Electrolysis to Treat Washing Fluid

s10-024

**Elisama Vieira dos Santos** (Institute of Chemistry, Federal University of Rio Grande do Norte, Natal, Brazil),  
Cristina Sáez, Carlos Alberto Martinez-Huitle, Pablo Cañizares, Manuel Andres Rodrigo

Combined soil washing and CDEO for the removal of oxyfluorfen from soils

s10-025

**Jiade Wang** (Environmental Engineering Center, Zhejiang University of Technology, Haangzhou, China),  
Mingming Zhou, Guolong Huang, Yongping Gan

Simultaneous Removal of COD and Ammonia Nitrogen using a Novel Electro-oxidation Reactor

s10-026

**Masafumi Yasuno** (Dept of Science of Environment and Mathematical Modeling, Doshisha University,  
Kyotanabe, Japan), Kenji Kawaguchi, Masatsugu Morimitsu

Development of Air Electrode Material Comprising Nano-oxide on Ni for MH/Air Secondary Battery

s10-027

**Min-Hsin Yeh** (School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, USA),  
Hengyu Guo, Long Lin, Zhen Wen, Zhaoling Li, Chenguo Hu, Zhong Lin Wang

Integrated Bundle Structure of Rolling Free Standing Triboelectric Nanogenerators and its Applications in  
Self-powered Copper Collecting Electrochemical system *via* Harvesting Hydropower

s10-028

**Chung-Yul Yoo** (Advanced Materials & Devices Laboratory, Korea Institute of Energy Research, Daejeon,  
Korea), Dae Sik Yun, Jong Hoon Joo, Ji Haeng Yu, Jong-Nam Kim, Hyung-Chul Yoon

Solid State Ammonia Synthesis – Present State and Perspective

s10-029

**Hsin-Fu Yu** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Jen-Yuan  
Wang, Min-Chuan Wang, Der-Jun Jan, You-Shiang Lin, Man-kit Leung, Kuo-Chuan Ho

A High Contrast Complementary Electrochromic Device with Sub-second Response Time

s10-030

**Antonio de Lucas Consuegra** (Chemical Engineering, Castilla La Mancha, Ciudad Real, Spain), Nuria  
Gutierrez-Guerra, Jesús Gonzalez-Cobos, Juan Carlos Serrano-Ruiz, José Luis Valverde

Electrochemical modification of Ni catalyst with alkali ionic conductors for CO<sub>2</sub> hydrogenation

## Symposium 11: New Important Frontiers in Molecular Electrochemistry

### Electrochemistry of new organometallic and coordination compounds

s11-001

**Masafumi Asahi** (Department of Energy and Environment, AIST, Ikeda, Japan), Shin-ichi Yamazaki, Zyun Siroma, Naoko Fujiwara, Tsukasa Nagai, Shinobu Itoh, Tsutomu Ioroi

Substituent Effects on Electrochemical Properties and Oxygen Reduction Reaction Activity of Copper Complexes

s11-002

**Zhaohui Huo** (Chemistry, Université de Strasbourg, Laboratoire d'Electrochimie, Strasbourg, France)

Original Porphyrin – Polyoxometalate Copolymers: Application for the Photocurrent Generation

s11-003

**Klaus Mathwig** (Groningen Research Institute of Pharmacy, University of Groningen, Groningen, Netherlands), Hamid Reza Zafarani, Sahana Sarkar, J. Matthäus Speck, Heinrich Lang, Serge Lemay, Oliver G. Schmidt

Potential-Dependent Electrochemical Spectroscopy of Multiferrocenylthiophenes in a Nanogap Sensor

s11-004

**Derck Schlettwein** (Institute of Applied Physics, Justus-Liebig-University Giessen, Giessen, Germany), Juliane Weissbecker, Andrei Loas, Sergiu M. Gorun

Influence of Decreased Intermolecular Coupling on the Electrochromic Switching-Rate of Substituted Phthalocyanine Thin Films

### Electron transfer

s11-005

**Carlos Frontana** (Investigacion, Centro de Investigacion y Desarrollo Tecnológico en Electroq, Pedro Escobedo, Mexico), Eduardo Martinez-Gonzalez

Electronic Structure Effects on Electron Transfer Controlled Hydrogen Bonding in Substituted Dinitrobenzene Electrogenated Anions As Receptors for 1,3-Diethylurea

### Molecular electrochemistry

s11-006

**John Horsley** (Chemistry, University of Adelaide, Adelaide, Australia)

The Correlation of Electrochemical Measurements and Molecular Junction Conductance Simulations in  $\beta$ -Strand Peptides

s11-007

**Cancan Huang** (Department of Chemistry and Biochemistry, University of Bern, Bern, Switzerland)

Tuning of charge transport in single molecule with the chemical and electrochemical methods

s11-008

**Miangang Li** (Chemistry Department, Xiamen University, Xiamen, China), Li Chen, Yunxin Zhong, Jiawei Yan, Bingwei Mao

Investigation of Electrode Reaction at Well-Defined Electrochemical Interfaces in Ionic Liquids

s11-009

**Hsin-Che Lu** (Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan), Ting-Hsiang Chang, Chung-Wei Kung, Sheng-Yuan Kao, Kuo-Chuan Ho

The Influence of Alkyl Chain Length of Viologens on the Performance of Their Electrochromic Devices

s11-010

**Jiri Ludvik** (Molecular Electrochemistry, J. Heyrovský Institute of Physical Chemistry ASCR, Prague, Czech Republic), Alan Liska

Structure-controlled Electrochemical Reduction of mono- and di-, nitro or nitroso Calix[4]arenes

s11-011

**Suzaliza Mustafar** (Chemistry, University of Tokyo, Tokyo, Japan), Kuo-Hui Wu, Kenji Takada, Ryojun Toyoda, Ryota Sakamoto, Hiroshi Nishihara

Synthesis of a  $\pi$ -conjugated porphyrin polymer film on electrode by electrooxidation of 5,15-di(4-aminophenyl)-10,20-diphenylporphyrinatozinc(II)

s11-012

**Laurent Ruhlmann** (Chemistry, Université de Strasbourg, Laboratoire d'Electrochimie, Strasbourg, France)  
Electrosynthesis Processes Based on Oxidative Couplings of Porphyrins for the Formation of  
Supramolecular Assemblies

s11-013

**Li Yang** (Department of Engineering Sciences, Uppsala University, Uppsala, Sweden), Xiao Huang, Adolf  
Gogoll, Maria Strømme, Martin Sjödin  
Terephthalate Functionalized Conducting Redox Polymers: Organic Anode Materials for Energy Storage

## Redox catalysis

s11-014

**Jingyuan Chen** (Department of Applied Physics, University of Fukui, Fukui, Japan), Wenwen Li, Koichi Aoki  
Catalytic reduction of dioxygen by ferrous hemin over formation of ferrous hemin -O<sub>2</sub> adduct

---

## Symposium 12: Physical Electrochemistry: Spectroscopic, Structural, and Theoretical Investigations of the Electrified Interface

---

### *In situ* spectroscopy (infrared, Raman, SHG, SFG, X-ray)

s12-001

**Jin-Chao Dong** (Chemistry, Xiamen University, Xiamen, China), Du-Hong Chen, Yue Li, Jin-Hui Meng, Yang  
Zhao, Chao-Yu Li, Jian-Feng Li  
*In-Situ* Monitoring the Electrocatalytic Reaction Processes at Platinum Single Crystal Electrode Using  
SHINERS

s12-002

**Kingo Itaya** (Frontier Institute for Interdisciplinary Sciences, Tohoku University, Sendai, Japan), Azhagurajan  
Mukkannan  
Application of an Ultra-high Resolution Optical Microscopy ~Imaging of Fast Reactions with Single  
Atomic Step Resolution~

s12-003

**Masaru Kato** (Faculty of Environmental Earth Science, Hokkaido University, Sapporo, Japan), Ken'ichi  
Kimijima, Mari Shibata, Hideo Notsu, Kazuya Ogino, Kiyoshi Inokuma, Narumi Ohta, Hiromitsu Uehara, Yohei  
Uemura, Nobuhisa Oyaizu, Tadashi Ohba, Satoru Takakusagi, Kiyotaka Asakura, Ichizo Yagi  
*In Situ* X-ray Absorption Fine Structure Spectroscopy of Dinuclear Copper Catalyst under Oxygen  
Reduction Reaction Conditions

s12-004

**Jan Philipp Kollender** (Institute for Chemical Technology of Inorganic Materials, Johannes Kepler University  
Linz, Linz, Austria), Andrei Ionut Mardare, Achim Walter Hassel  
*In-situ* monitoring of metal dissolution during anodisation of Al and Ti

s12-005

**Kamila Lepicka** (Department of Physical Chemistry of Supramolecular Complexes, Institute of Physical  
Chemistry Polish Academy of Sciences, Gdańsk, Poland), Piotr Pieta, Pawel Borowicz, Alexey Popov,  
Włodzimierz Kutner  
Spectroelectrochemical characterization of a salicilidene Ni(II) redox conducting polymer for  
supercapacitors

s12-006

**Shawn D. Lin** (Chemical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan),  
Bing-Joe Hwang, Yaw-Terng Chern  
*In Situ* DRIFTS Analysis of SEI formation over Cathodes at Elevated Temperature

s12-007

**Kei Murakoshi** (Department of Chemistry, Hokkaido University, Sapporo, Japan), Yumi Wakisaka, Mai Takase, Hiro Minamimoto, Satoshi Yasuda

Optical Force Applied to Molecules at Nanogap of Metal Nanodimer

s12-008

**Martin Pfaffeneder-Kmen** (Department of Physical Chemistry, University of Vienna, Vienna, Austria)

The Redox Behaviour of Graphene Oxide: A Spectroelectrochemical Study

s12-009

**Bin Ren** (Department of Chemistry, Xiamen University, Xiamen, China), Zhi-Cong Zeng, Sheng-Chao Huang, Teng-Xiang Huang, Jin-Hui Zhong, Mao-Hua Li, Xiang Wang

Electrochemical Tip-Enhanced Raman Spectroscopy (EC-TERS)

s12-010

**Manuela Rueda** (Department of Physical Chemistry, University of Seville, Seville, Spain), Francisco Prieto, Julia Alvarez-Malmaro, Jose M. Ors

ATR-SEIRAS and Electrochemical Study of the Tautomeric Equilibrium of Adsorbed Thymine on Gold Electrodes

s12-011

**Ken-ichi Uchida** (Catalysis Research Center, Hokkaido University, Sapporo, Japan), Kenta Motobayashi, Kazuya Minami, Naoya Nishi, Tetsuo Sakka, Masatoshi Osawa

Potential-Dependent Structure of [BMIM]<sub>(1-x)</sub>Li<sub>x</sub>[FSA] on a Gold Electrode: A Surface-Enhanced Infrared Study

s12-012

**De-Yin Wu** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China), Yuan-Fei Wu, Zhong-Qun Tian

Electrochemical Adsorption and Surface-Enhanced Raman Spectroscopy on Nanostructured Electrodes

s12-013

**Momo Yaguchi** (Section of Interfacial Chemistry, Catalysis Research Center, Sapporo, Japan), Marc T.M. Koper, Masatoshi Osawa

Electrocatalysis of Formic Acid Oxidation on Gold and Platinum: Where Does the Crucial Activity Difference Come From?

## Physical electrochemistry

*Ab initio* lattice stability of the  $x\text{Li}_2\text{MnO}_3 \cdot (1-x)\text{Li}(\text{Ni}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3})\text{O}_2$  composite-layered cathode materials for lithium-ion batteries

s12-028

**Oksana Limanovskaya** (Urals Federal University, Ekaterinburg, Russia), Valentin Nekrasov, Andrey Suzdaltsev, Andrey Khramov, Yuriy Zaikov

Modeling of quasi-stationary process at the Platinum anode in the KF–NaF–AlF<sub>3</sub>–Al<sub>2</sub>O<sub>3</sub>

## Symposium 13: Molecular Systems for Energy Conversion

### Electrodes materials

s13-001

**Abdullah Al Mayouf** (Chemistry, King Saud University, Riyadh, Saudi Arabia), Mohamed Ali Ghanem, Maged Naji Shaddad, Prabhakarn Arunachalam, Mansour Al Hoshan, Mark T. Weller, Frank Marken

Photoelectrochemical characterization of ZnLaTaON based electrodes for water oxidation reaction

## Symposium 14: Modeling, Design and Characterization of Nanostructured, Electroactive and Multifunctional Materials

### Composites

s14-001

**Katarzyna Krukiewicz** (Department of Physical Chemistry and Technology of Polymers, Silesian University of Technology, Gliwice, Poland), John Bulmer, Dawid Janas, Krzysztof Koziol, Jerzy Zak

Nucleation and Growth of PEDOT on the Surface of Horizontally Aligned Carbon Nanotubes

### Electroactive materials

s14-002

**Rajendranath Kirankumar** (Medicinal and Applied Chemistry, Kaohsiung Medical University, Kaohsiung, Taiwan)

Electropolymerized Carbazole-Containing Ionic Liquid

s14-003

**Jing-Ting Liao** (Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan), Sin-Syu Liao

Electrical Characteristics of Raw Si-based Powders for Li-ion Electrode by Kelvin Probe Force Microscopy (KPFM) and Electrostatic Force Microscopy (EFM)

s14-004

**Mikhail A. Vorotyntsev** (Chemistry Department, D. Mendeleev University of Chemical Technology of Russia, Moscow, Russia), Dmitry V. Konev, Olga I. Istakova, Dinara K. Khayrullina

Study of Effect of Various Solvents on the Electropolymerization Process of Mg(II) Porphine and Electroactive Properties of Polyporphine Films

### Electrocatalysis

s14-005

**Li Li** (School of Chemistry and Chemical Engineering, Chongqing University, Chongqing, China), Yao Nie, Siguo Chen, Wei Ding, Xueqiang Qi, Feng Shi, Zidong Wei

Insight into the effect of oxygen vacancy concentration on the catalytic performance of MnO<sub>2</sub>

**Functional and nanostructured materials**

s14-006

**Jung Sang Cho** (Department of Materials Science and Engineering, Korea University, Seoul, Korea)  
Advanced Anode Material with Bubble-Nanorod-Structured Metal Oxide-Carbon Composite Nanofibers

s14-007

**Jooyoun Jeong** (Department of Chemical Engineering, Pohang University of Science and Technology (POSTECH), Pohang, Korea), Seongbeen Kim, Yongchai Kwon  
Mesocellular Carbon based Electrodes for High-Performance Vanadium Redox Flow Battery

s14-008

**Joonhee Kang** (Energy systems Engineering, DGIST, Daegu, Korea), Byungchan Han  
First principles study of thermal stability of LiNiO<sub>2</sub> materials coated with ultrathin amorphous Al<sub>2</sub>O<sub>3</sub> layers

s14-009

**Yann Leroux** (Institut des Sciences Chimiques de Rennes, CNRS - Université de Rennes 1, Rennes Cedex, France), Philippe Hapiot  
Nanostructured Monolayers on Carbon Substrates

s14-010

**Aiping Liu** (Center for Optoelectronics Materials and Devices, Zhejiang Sci-Tech University, Hangzhou, China)  
GO/rGO Microelectrode Arrays with Adjustable Electrochemical Activity and Biocompatibility for Highly Sensitive Detection of Hydrogen Peroxide Released by Living Cells

s14-011

**Hiro Minamimoto** (Department of Applied Chemistry, Graduate School of Engineering, Osaka University, Osaka, Japan), Haruyasu Irie, Taro Uematsu, Tetsuya Tsuda, Akihito Imanishi, Shu Seki, Susumu Kuwabata  
Fabrication of 3D Micro/Nano-Polymer and Metal Structures in Room-Temperature Ionic Liquid by Electron Beam Irradiation

s14-012

**Herenilton Oliveira** (Chemistry, Universidade de São Paulo, Ribeirão Preto, Brazil), Laura Novais, Raíssa Camargo, Paulo Noronha Filho  
Glassy Polymeric Carbon/Fe<sub>x</sub>C<sub>y</sub> and Carbon/Co<sub>x</sub>C<sub>y</sub> Nanocomposites: Electrochemical and Magnetic Properties

s14-013

**Emmanuel Rocca** (Institut Jean Lamour UMR CNRS, Université de Lorraine, Vandoeuvre Les Nancy, France), Hadri Faiz, François Mirambet, Solenn Reguer  
Electrochemical properties of nano functionalized iron oxyhydroxide: strategies for the corrosion protection of rusted steels

s14-014

**Jinju Song** (Materials Science and Engineering, Chonnam National University, Gwangju, Korea), Jihyeon Gim, Sungjin Kim, Jeonggeun Jo, Joseph Paul Baboo, Seokhun Kim, Sohyun Park, Dongyun Kim  
Pyro-Synthesis of Functional Nanocrystals

s14-015

**Lu-Hsiang Yin** (Chemical Engineering, National Taiwan University, Taipei, Taiwan), Sheng-Yuan Kao, Chung-Wei Kung, Ting-Hsiang Chang, Kuo-Chuan Ho  
An Electrochromic Copolymer with One-dimensional Nanowire Arrays

**Materials electrosynthesis**

s14-016

**Na Tian** (Department of Chemistry, Xiamen University, Xiamen, China), Jia-Huan Du, Shi-Gang Sun  
Electrochemical shape transformation of Pt nanocrystals with high-index facets

**Molecular architectures**

s14-017

**Laurence Hardwick** (Chemistry, University of Liverpool, Liverpool, United Kingdom), Scott Lewis, Ming Liu, Linjiang Chen, Iain Aldous, Marc Little, Sam Chong, Andy Cooper  
Understanding Proton Conductivity within Porous Organic Cage Networks

**Nanoparticles**

s14-018

**C. Y. Ho** (Mechanical Engineering, Hwa Hsia University of Technology, New Taipei, Taiwan), B.C. Chen, M. Y. Wen, Y. H. Tsai, H. H. Ku

Electrical Heating Effect of Carbon Nanoparticles as Electrodes in the Charging Process

s14-019

**Hongjiao Li** (Chemistry Department, Technische Universität München, Munich, Germany), Yunchang Liang, Wenbo Ju, Marian D. Rötzer, Florian F. Schweinberger, Ulrich Stimming, Ueli Heiz, Oliver Schneider

Activity and Stability of Pt Clusters supported on Au(111) for Electro-oxidation of Formic Acid

s14-020

**Shuo Liu** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China)

Electrochemical Reaction of Single Nanoparticle

s14-021

**Mesfin Haile Mamme** (Research Group Electrochemical and Surface Engineering, Vrije Universiteit Brussel, Brussels, Belgium), El Amine Mernissi Cherigui, Olga Dolgikh, Jon Ustarroz, Herman Terry, Johan Deconinck

A Finite Element Simulation of the Electrochemical Growth of Single Nanoparticle

**Organic-inorganic and polymer-inorganic hybrids**

s14-022

**Chien-Hong Lin** (Chemistry Division, Institute of Nuclear Energy Research, Longtan, Taiwan)

Amino-Silica Modified Nafion Membrane for Vanadium Redox Flow Battery

## Symposium 15: Electrochemical Engineering from a Quantum Description to the Plant Modeling: Experiments and Design across Length Scale

---

**Design**

s15-001

**Hung-Lung Chou** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei, Taiwan)

Combined Experiment and DFT Investigations of Catalytic Activities into Pt-based Electrocatalysts for Fuel Cell Applications

s15-002

**Alejandro A. Franco** (Laboratoire de Réactivité et Chimie de Solides (LRCS), Université de Picardie Jules Verne & CNRS, Amiens, France), Kan-Hao Xue, Claude Guery, Patrik Johansson, Mathieu Morcrette

A flexible framework for solving transport in lithium sulfur batteries

s15-003

**Hyung-Kyu Lim** (Graduate School of EEWS, Korea Advanced Institute of Science and Technology, Daejeon, Korea), Hyungjun Kim

Discover a Role of Ionic-Liquid in Electrochemical CO<sub>2</sub> Reduction by Using QM/MM Method

s15-004

**Yinghui Yin** (Laboratoire de Réactivité et Chimie des Solides (LRCS), Université de Picardie Jules Verne, Amiens, France), Matias A. Quiroga, Alejandro A. Franco

Multiparadigm Simulation of Electrochemical Energy Devices: The Fuel Cell Membrane Degradation

## Experiments

s15-005

**Hye Youn Han** (Chemistry, Kyungpook National University, Daegu, Korea), Farhana Sharmin Diba, Hye Jin Lee

Electrochemical Studies at an Interface between Two Immiscible Electrolyte Solutions for CO<sub>2</sub> Reduction

s15-006

**Changbin Im** (Ertl Center for Electrochemistry and Catalysis, Gwangju Institute of Science and Technology, Gwangju, Korea), Jae Kwang Lee, Jaeyoung Lee

Synthesis of High Ionic Conductive L<sub>7</sub>La<sub>3</sub>Zr<sub>2</sub>O<sub>12</sub> Solid Electrolyte by a Sol-gel Process

---

## Symposium 16: Supramolecular Electrochemistry for Analysis, Medicine and Biological Sciences

---

### Inclusion complexes

s16-001

**Mei-Jywan Syu** (Chemical Engineering, National Cheng Kung University, Tainan, Taiwan), Yao-Wei Hsu

On the Synthesis of Zinc-Tetrapyrrolylporphine Complex for the Electrochemical Recognition of Bilirubin in Serum

### Molecular recognition

s16-002

**Yu Cheng** (Dept. Biomedical Engineering, National Cheng Kung University, Tainan, Taiwan)

A Rapid Detection of Biomarkers Applied by Electrochemical Biosensor Accelerated with an AC Electrokinetic Manipulation

s16-003

**Flavio Maran** (Chemistry, University of Padova, Padova, Italy), Anna Pellattiero, Federico Polo, Giuseppe Toffoli, Aline S. C. Fabricio, Massimo Gion

Ultrasensitive Electrochemical Detection of the Cancer Biomarker CA19.9

s16-004

**Manuela Rueda** (Department of Physical Chemistry, University of Seville, Seville, Spain), Julia Alvarez-Malmagro, Francisco Prieto

DNA Bases Co-Adsorption at Gold Electrodes. An *in-situ* FT-IR Spectro-Electrochemical Study

### Redox therapy, drug carriers

s16-005

**Marilia Goulart** (Instituto de Química e Biotecnologia, Universidade Federal de Alagoas, Maceio, Brazil), Thaissa Silva, Camila Vasconcelos, Fabricia Ferreira, Chaquip Netto, Paulo Costa

The Yin-Yang Nature of Biologically Active Pterocarpanquinones: ROS Release and Alkylating Ability also Revealed by Electrochemistry

s16-006

**Katarzyna Krukiewicz** (Department of Physical Chemistry and Technology of Polymers, Silesian University of Technology, Gliwice, Poland), Tomasz Jarosz, Barbara Bednarczyk-Cwynar, Piotr Ruszkowski, Jerzy Zak

Local Delivery of Biologically Active Compounds Based on Conjugated Polymer Matrices

### Self-assembly

s16-007

**Hiromi Yoda** (Graduate School of Engineering, Kanagawa Institute of Technology, Atsugi, Japan), Ayumi Koike-Takeshita

Application of GroEL Complexes as Nano-sized Cargo

## Symposium 17: Novel in Situ in Operando Methods

### Energy materials and electrocatalysts

s17-001

**Patrick Faubert** (Department of Microsystems Engineering – IMTEK, Albert-Ludwigs-University, Freiburg, Germany), Ivan Kondov, Claas Müller, Holger Reinecke, Peter Smyrek, Johannes Pröll, Wilhelm Pfleging  
Analysis of the Surface Structure and Catalytic Behavior of Cr-modified Ni Surfaces for Fuel Cells

s17-002

**Tzu-Ho Wu** (Chemistry, University of Liverpool, Liverpool, United Kingdom), Jia-Cing Chen, Chun-Tsung Hsu, Laurence Hardwick  
Cation Effect on Ni(OH)<sub>2</sub> Phase Transformation

### In-situ microscopy and spectroscopy

s17-003

**Ju-Hsiang Cheng** (Department of Chemical Engineering, National Taiwan University of Science and Technology, Taipei City, Taiwan), Ming-Hsien Lin, Chun-Yi Wu, Chun-Chieh Wang, Yen-Fang Song, Bing-Joe Hwang  
A Study on the Hollow Cubic SnO<sub>2</sub> as Anode Material for Lithium-ion Battery by Transmission X-ray Microscopy

s17-004

**Yi-Ting Hsieh** (Department of Chemistry, National Cheng Kung University, Tainan, Taiwan)  
Electrodeposition of Cu-Sn Hexagonal Tubes from Room Temperature Ionic Liquid and its *In-Situ* Scanning Electron Microscopy Study

s17-005

**Chen-Yuan Lu** (Materials Science and Engineering, National Cheng Kung University, Tainan, Taiwan), Yu-Lun Cheng  
Investigation of Solid Electrolyte Interface of Silicon Electrode in Li-ion Batteries by Dual-Electrode Scanning Probe

### Multi-technique approaches

s17-006

**Nicolas Jäckel** (Energy Materials, INM- Leibnitz-Institute for New Materials, Saarbrücken, Germany), Nethanel Shpigel, Sergey Sigalov, Mikhael D. Levi, Daniel Weingarth, Doron Aurbach, Volker Presser  
*In-situ* monitoring of elastic properties of common binders in Lithium ion batteries *via* electrochemical quartz microbalance with dissipation and dilatometry

### Structural transformations

s17-007

**Keiji Shimoda** (Office of Society-Academia Collaboration for Innovation, Kyoto University, Uji, Japan), Miwa Murakami, Hideyuki Komatsu, Hajime Arai, Yoshiharu Uchimoto, Zempachi Ogumi  
*In situ* and *ex situ* NMR observation of delithiation/lithiation behavior of LiNi<sub>0.5</sub>Mn<sub>1.5</sub>O<sub>4</sub>

---

## Symposium 18: General Session

---

### Analytical electrochemistry

s18-001

**Ching-Hsiang Chen** (Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology, Taipei City, Taiwan), Agnes Purwidyantri, Bing-Joe Hwang, Ya-Chung Tian, Chi-Hui Cheng, Chao-Sung Lai

Fabrication of AuNPs Array on ITO electrode *via* Nanospheres Lithography and its DNA Sensing Applications

s18-002

**Arturo-de-Jesus García-Mendoza** (Analytical Chemistry, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico), Adrián De-Santiago-Zárate, José-Alejandro Baeza-Reyes

Minimal instrumentation electroanalytical experimental approach

s18-003

**Arturo-de-Jesus García-Mendoza** (Analytical Chemistry, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico), Julio-César Aguilar-Cordero

Construction and evaluation of reference electrodes for imidazolium-based ionic liquids. An analytical description

s18-004

**Abdulkadir Levent** (Analytical Chemistry, Batman University, Batman, Turkey)

Simultaneous Determination of Ascorbic Acid, Epinephrine and Uric Acid by Differential Pulse Voltammetry on a Disposable Pencil Graphite Electrode

s18-005

**Abdulkadir Levent** (Analytical Chemistry, Batman University, Batman, Turkey)

Simultaneous Determination of Ascorbic acid, Norepinephrine and Uric acid by Differential Pulse Voltammetry on a Disposable Pencil Graphite Electrode in the Pharmaceutical Formulations and Human Urine Samples

s18-006

**Adeline Loo** (Division of Chemistry & Biological Chemistry, SPMS, NTU, Nanyang Technological University, Singapore, Singapore), Alessandra Bonanni, Adriano Ambrosi, Martin Pumera

Molybdenum Disulfide (MoS<sub>2</sub>) Nanoflakes as Inherently Electroactive Labels for DNA Hybridization Detection

s18-007

**Masakuni Takahashi** (Chemical Engineering, Tokyo National College of Technology, Hachioji, Japan), Hidenobu Shiroishi, Genichiro Nakamura, Tatsuhiko Okada

Evaluation of oxygen reduction properties by ring-disk flow electrode

s18-008

**Wei Zhe Teo** (Chemistry & Biological Chemistry, Nanyang Technological University, Singapore, Singapore), Martin Pumera

Fate of Silver Nanoparticles in Natural Waters; Integrative Use of Conventional and Electrochemical Analytical Techniques

s18-009

**Tadaharu Ueda** (Applied Science, Kochi University, Kochi, Japan), Takashi Okumura, Yukino Tanaka, Saki Akase, Mina Taniguchi, Tomoko Shimamura, Hiroyuki Ukeda

Development of New Electrochemical Evaluation Method for Antioxidant Capacity with Polyoxometalates as Potential Probes

s18-010

**Hiroyuki Ueda** (Graduate School of Science and Technology, Kumamoto University, Kumamoto, Japan), Katsuhiko Nishiyama, Soichiro Yoshimoto

Electrochemical Redox Behavior of Cobaltocenium in Imidazolium-based Ionic Liquids with Various Alkyl Chain Length

s18-011

**Colin Hong An Wong** (Division of Chemistry & Biological Chemistry, SPMS, NTU, Nanyang Technological University, Singapore, Singapore), Zdenek Sofer, Marie Kubešová, Jan Kucera, Stanislava Matejková, Martin Pumera

Inadvertent contamination of graphene materials: Synthetic routes introduce a whole spectrum of unanticipated metallic elements

s18-012

**Guan Xiao-Rui** (China University of Petroleum, Qingdao, China), Zhang Dalei, Jin You-hai, Wang Jian-jun  
Electrochemical Characterization and Molecular Dynamics Simulation on Corrosion Inhibition of Quinoline

## Bioelectrochemistry

s18-013

**Seung-Ryong Kwon** (Chemistry, Seoul National University, Seoul, Korea), Sung Yul Lim, Taek Dong Chung  
Reverse Electrodialysis (RED) as a New Electrical Power Source for a Drug Delivery System

s18-014

**Pu-Wei Wu** (Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan), Chai-Wei Chung, Yong-Min Chen, Po-Chun Chen  
Multilayer Deposition of Iridium Oxide for Biocompatible Stimulating Electrode Application

## Electrochemical energy conversion and storage

s18-015

**Hao Huang** (Department of Engineering Sciences, Uppsala University, Uppsala, Sweden), Christoffer Karlsson, Rikard Emanuelsson, Maria Strømme, Adolf Gogoll, Martin Sjödin  
Quinone Based Polypyrroles for Energy Storage Materials

s18-016

**Moon-Sung Kang** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Do-Hyeong Kim, Eun-Hye Jang, Yu-Jin Kim, Jin-Soo Park  
Optimization of Ionomer Membrane Characteristics for High Performance Reverse Electrodialysis

s18-017

**Zhenhai Liang** (College of Chemistry and Chemical Engineering, Taiyuan University of Technology, Taiyuan, China), Xian Liu, Xuan Jian, Huimin Yang  
A Novel Photoelectrocatalytic Approach for Regenerating NaOH by a BiOCl/bipolar Membrane Sandwich Structure

s18-018

**Yingbin Lin** (College of Physics and Energy, Fujian Normal University, Fuzhou, China), Zhigao Huang  
Synthesis and Electrochemical Performances of Hollow Spherical  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  for Lithium Ion Batteries

s18-019

**Shohei Suzuki** (Department of Life Science and Sustainable Chemistry, Faculty of Engineering, Tokyo Polytechnic University, Atsugi, Kanagawa, Japan), Masaru Ogasawara, Noritoshi Nanbu  
Physical and Electrochemical Properties of Quaternary Ammonium Compounds in Highly Concentrated Solutions

## Electrochemical materials science

s18-020

**Aicheng Chen** (Department of Chemistry, Lakehead University, Thunder Bay, Canada), Suresh Konda, Cassandra Ostrom, Brian Adams, Robert Asmussen  
Synthesis and Electrochemical FTIR Study of Nanoporous Palladium-Based Bimetallic Catalysts

s18-021

**Jin Cui** (MESA+ Institute for Nanotechnology, University of Twente, Enschede, Netherlands), Klaus Mathwig, Serge Lemay  
Concentration Rectification in Nanofluidic Transducers

s18-022

**Alex Yong Sheng Eng** (Chemistry and Biological Chemistry, Nanyang Technological University, Singapore, Singapore), Adriano Ambrosi, Zdenek Sofer, Petr Simek, Martin Pumera

Electrochemistry of Transition Metal Dichalcogenides: Dependence on Composition and Exfoliation Method

s18-023

**Robert Hillman** (Department of Chemistry, University of Leicester, Leicester, United Kingdom), Rachel Sapstead, Natalie Corden, Emma Palin

Electrochromic Copolymer Film Deposition for Visualization of Latent Fingerprints on Stainless Steel Surfaces

s18-024

**Jia-Lin Jhan** (Department of Chemical Engineering and Materials Science, Yuan Ze University, Taoyang, Taiwan), Leo Chau-Kuang Liao, Po-Chin Tseng

Effects of constant on-off current pulse on the properties of Cu<sub>2</sub>O films fabricated by electrochemical deposition method

s18-025

**Masahiro Kobayashi** (Chemical Engineering, Tokyo National College of Technology, Hachioji, Japan), Hidenobu Shiroishi, Masahiko Kijima, Yumi Tanaka, Jun Kuwano

Synthesis of nanoparticle-type new proton conductor made from d-glucose by a hydrothermal method

s18-026

**Hsueh Ming Liu** (Chemistry, National Central University, Taoyuan City, Taiwan), Cheng-Gang Wu, Diganta Saikia, Hsien-Ming Kao

Synthesis and Characterization of Polyether Diamine based Organic-Inorganic Hybrid Solid Electrolyte for Electrochromic Devices

s18-027

**Hsueh Ming Liu** (Chemistry, National Central University, Taoyuan City, Taiwan), Kwo-Wei Lou, Diganta Saikia, Hsien-Ming Kao

Synthesis, Structure Characterization, Electrical and Thermodynamic Properties of Comb Structured Organic-Inorganic Hybrid Solid Polymer Electrolytes

s18-028

**Toshiyuki Matsunaga** (Academia Collaboration for Innovation, Kyoto University, Kyoto, Japan), Hideyuki Komatsu, Keiji Shimoda, Taketoshi Minato, Masao Yonemura, Takashi Kamiyama, Shunsuke Kobayashi, Takeharu Koto, Tsukasa Hirayama, Yuichi Ikuhara, Hajime Arai, Yoshio Ukyo, Yoshiharu Uchimoto, Zempachi Ogumi

Significant cation mixing in the transition-metal layer of Li<sub>2</sub>MnO<sub>3</sub>

s18-029

**Masaru Ogasawara** (Department of Life Science and Sustainable Chemistry, Faculty of Engineering, Tokyo Polytechnic University, Atsugi, Kanagawa, Japan), Shouhei Suzuki, Noritoshi Nanbu

Relative Permittivities of Binary Solvent Mixtures

s18-030

**Kayato Ooya** (Chemical Engineering, Tokyo National College of Technology, Hachioji, Japan), Hidenobu Shiroishi, Morihiro Saito, Yumi Tanaka

Characteristics of an intermediate-temperature fuel cell using proton conductive ZrO<sub>2</sub>-1.6P<sub>2</sub>O<sub>5</sub>-doped ZnO-2P<sub>2</sub>O<sub>5</sub> hybrid electrolyte

## Electrochemical process engineering and technology

s18-031

**Kazuhisa Azumi** (Graduate School of Engineering, Hokkaido University, Sapporo, Japan), Hayato Yoshikawa, Kazunori Suetake

Electrochemical CO<sub>2</sub> Reduction in EMIN-TFSI Ionic Liquid

s18-032

**Gha-Young Kim** (Nuclear Fuel Cycle Process Development, Korea Atomic Energy Research Institute, Daejeon, Korea), Jisun Shin, Si-Hyung Kim, Do-Hee Ahn, Seungwoo Paek

Actinide Recovery using Anode-Liquid Cathode Module for Pyroprocessing

s18-033

**Do-Hyeong Kim** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Eun-Hye Jang, Jin-Soo Park, Moon-Sung Kang

Development of Novel Bipolar Membranes for Efficient Electro-Adsorptive Deionization

s18-034

**Do-Hyeong Kim** (Department of Environmental Engineering, Sangmyung University, Cheonan, Korea), Yu-Jin Kim, Jin-Soo Park, Moon-Sung Kang

Determination of optimal design parameters for preparing ion-exchange membranes for efficient redox flow batteries

s18-035

**Jooyul Lee** (Electrochemistry Department, Korea Institute of Materials Science, Changwon, Korea), Yongsoo Jeong

Manufacturing of Micro Probe Tip through Ni Alloys Electroplating

s18-036

**Jau-Kai Wang** (Applied Chemistry and Material Science, Fooyin University, Kaohsiung, Taiwan), Yan-Ru Wang, Ying-Ting Wang

A study on Supercritical Electrolytic Polishing Process for Stainless steel substrates

s18-037

**Jen-Yuan Wang** (Physics Division, Institute of Nuclear Energy Research, Taoyuan, Taiwan), Min-Chuan Wang, Hsin-Fu Yu, Der-Jun Jan, Kuo-Chuan Ho

A Flexible all-solid-state Electrochromic Device with Polymeric Crystal Composite Electrolyte and WO<sub>3</sub>/NiO Complementary System

## Physical electrochemistry

s18-038

**B.C. Chen** (Chinese Medicine, Buddhist Dalin Tzu Chi General Hospital, Chiayi, Taiwan), C. Y. Ho, H. H. Ku, M. Y. Wen, W. C. Wu, Y. H. Tsai

Electrical Current-Induced Thermal Characteristics in a Carbon Nanotube

s18-039

**Keiichi Nishihata** (Advanced Engineering Faculty, National Institute of Technology, Wakayama College, Wakayama, Japan), Katsuhiko Tsunashima, Masahiko Matsumiya

Preparation and Physicochemical Properties of Room-Temperature Phosphonium Ionic Liquids Based on Tetracyanoborate Anion

s18-040

**Marcin Opallo** (Department of Electrode Processes, Institute of Physical Chemistry Polish Academy of Sciences, Warszawa, Poland), Justyna Jedraszko, Wojciech Nogala, Wojciech Adamiak, Saustin Dongmo, Gunther Wittstock, Hubert Girault

(Electro)catalysis at Room Temperature Ionic Liquid/Water Interface: H<sub>2</sub>O<sub>2</sub> Generation

s18-041

**Wei Wang** (College of Chemistry and Chemical Engineering, Xiamen University, Xiamen, China), Fang-Fang Wang, Jie Zhang, Bao-Fa Su, Dongping Zhan, Zhong-Qun Tian

Quantifying Surface Diffusion by Nanoelectrode

# The International Society of Electrochemistry

The International Society of Electrochemistry (ISE) was founded in 1949 by leading European and American electrochemists to serve the growing needs of electrochemistry. At that time only a handful of scientists were members of the society – known as CITCE (Comité International de Thermodynamique et Cinétique Electrochimiques). Since then ISE has evolved and comprises now more than 3500 individual members, from 72 countries, and is organized in 44 Regional Sections. Both industrialised and developing countries from all five continents are represented. ISE is, therefore, a truly world-wide organisation. ISE is a non-profit-making organisation with its seat in Lausanne, Switzerland.

The International Society of Electrochemistry (ISE) is devoted to the advancement of electrochemical science and technology through the promotion of international contacts and the dissemination of scientific knowledge. For this ISE organises Annual and Topical Meetings which are held in different countries each year and which cover a wide range of current topics in fundamental and applied electrochemistry. The activities of ISE include the sponsoring of regional meetings, and of special meetings of limited participation devoted to particular subjects. A scientific journal, *Electrochimica Acta*, is edited by ISE and supplied to its members at a special rate. Individuals, non-profit organisations, industrial companies and learned societies may become members of ISE. The administration of ISE is done by an Executive Committee, periodically elected by all members. The Regional Representatives together with the Division Officers form the ISE Council which advises the Executive Committee. The scientific activities of ISE are grouped into Scientific Divisions. They are organised and co-ordinated by the Committee of Division Officers headed by the President Elect. Upon joining ISE each member indicates his/her divisional interests.

The history of the International Society of Electrochemistry (ISE) is described in a series of articles published in Volume 45 of *Electrochimica Acta* and available on the web site of the Society (<http://www.ise-online.org/geninfo/history.php>).

## Why you should join ISE

ISE membership provides a number of advantages which can be summarized as follows:

- Individual members can get reduced subscription rates for the following journals:  
*Electrochimica Acta* (online),  
*Journal of Electroanalytical Chemistry* (online),  
*Electrochemistry Communications* (online),  
*Bioelectrochemistry* (online),  
*Journal of Power Sources* (online),  
*Journal of Applied Electrochemistry* (print),  
*Electroanalysis* (print),  
*Journal of Solid State Electrochemistry* (print) for personal use.  
There is also a Discounted Package available consisting of the *Journal of Electroanalytical Chemistry*, *Electrochemistry Communications*, and *Bioelectrochemistry* (online).
- Reduced registration fees at ISE Meetings
- Access to the "members restricted area" of the ISE website
- Access to the full membership directory with all members addresses

## How to become an ISE member

Becoming an ISE member is simple: you will find a Membership Application Form on the Society web site (at the address: [http://members.ise-online.org/members/new\\_members.php](http://members.ise-online.org/members/new_members.php)), which you can fill in and submit online. In the application form you will have to select up to three Divisions and indicate two sponsoring ISE members. Should it be difficult for you finding these sponsors, please write to the Executive Secretary of the Society Dr. M. Musiani, e-mail: [m.musiani@ieni.cnr.it](mailto:m.musiani@ieni.cnr.it).

## Membership fees

Individual yearly membership fees are 40 EUR for members above 30 years of age, and 10 EUR for members of age 30 or less and for Emeritus members.

---

## ISE Organization

---

### Executive Committee

The Executive Committee is entrusted with the management of the Society.

### ISE Office

The ISE Office performs all administrative tasks related to the operation of the Society. It is located in Switzerland, and managed by an Executive Secretary.

The ISE Office serves as the primary contact for members and non-members.

### Division Officers

The scientific activities of ISE are grouped into seven Scientific Divisions and a New Topics Committee. The divisions are headed by a Chairperson assisted by a Past Chair, a Chair Elect and two Vice Chairs. Their role is to promote and represent the scientific interests of the division and its members, for example through contributing to the organization of Annual, Topical and other Society meetings.

### Regional Representatives

In each country or group of countries having fifteen members or more, a national or regional section of ISE may be formed. Each section has a Regional Representative.

### Council

The ISE Council is an Advisory Body. The voting members of the Council consist of three Officers from each Division and all the Regional Representatives. All persons constituting the Council are elected by the members of the Society.

### Scientific Meetings Committee

The Scientific Meetings Committee plans and oversees the organization and sponsorship of scientific meetings within the broad field of electrochemistry.

### Fellows Nominating Committee

The Fellows Nominating Committee is a standing committee which proposes names to the Executive Committee for the title of ISE Fellow. It is also responsible for identifying candidates for honorary membership.

### Publications Committee

The Publication Committee, a standing committee of ISE, acts as an advisory board to the Executive Committee on publication matters.

## ISE Executive Committee

### President

**Christian Amatore**, Paris, France (2015-2016)

Representation of ISE. Chairperson of Executive Committee, Council and General Assembly

### President Elect

**Philip N. Bartlett**, Southampton (2015-2016)

Chairperson of Committee of Division Officers. Coordination of scientific program of future Annual Meetings, supervision of Division Officers' activities

### Immediate Past President

**Hasuck Kim**, Seoul, Korea (2015-2016)

Chairperson of Executive Committee in the absence of the President

### Vice Presidents

**Justin Gooding**, Sidney, Australia (2013-2015)

Responsible for relations with other Societies

**Plamen Atanasov**, Albuquerque, NM, USA (2015-2017)

Responsible for Corporate and Corporate Sustaining Members

**Katharina Krischer**, München, Germany (2015-2017)

Responsible for Educational Activities in ISE

**Yunny Meas**, CIDETEQ, Querétaro, Mexico (2014-2016)

Responsible for Regional Sections

### Secretary General

**Manuela Rueda** (2015-2017)

#### *General tasks*

Ensuring continuity and efficiency of scientific policy. Coordination of tasks of Vice Presidents.

Identification of new developments in electrochemistry and possible new scientific and nonscientific activities. Scientific matters not handled by the President or President Elect.

#### *Tasks in collaboration with ISE Office*

Ensuring that constitution, bylaws, guidelines, schedules etc. are observed. Preparation of Annual Reports.

Collection of information for newsletters and coordination of actions.

#### *Annual and Topical ISE Meetings*

Coordination of Meetings (location, time, topics). Representative of Executive Committee and advisor to Local Organising Committees for nonscientific matters (location, facilities, control of financial planning, schedule, publicity).

### Treasurer

**Bernard Tribollet**, Paris, France (2014-2016)

Responsible for the administration and the management of the assets and property of the Society, preparation of budgets and financial reports, financial planning, investment policy, supervision of financial matters of Annual and Topical ISE Meetings.

### Executive Secretary

**Marco Musiani**, Padova, Italy (2014-2018)

Responsible for maintaining the ISE calendar, assisting with organizing the business and financial arrangements for Annual and Topical Meetings, organising committee appointments, assisting the Secretary General with Society elections, recruiting new members, and co-ordinating Executive Committee meetings. Drafts ISE documents, acts as web page editor, maintains ISE archives and records, and serves as the contact person for members (particularly at ISE meetings).

## Scientific Divisions of ISE

### Division 1 – ANALYTICAL ELECTROCHEMISTRY

Experimental and theoretical aspects of the analytical process in which electrochemistry has a role, including sample collection / processing, separation, and species identification and quantitation.

Chair: F. Bedioui, Past Chair: A. Downard, Chair Elect: D. Mandler, Vice-Chairs: P. Baker and J. Pingarron

### Division 2 – BIOELECTROCHEMISTRY

Aspects of electrochemistry and electroanalysis characterizing biological processes at the molecular level and relevant to the mechanisms of biological regulation of cells.

Chair: R. Bilewicz, Past Chair: W. Shin, Chair Elect: F. Lisdat, Vice-Chairs: D. Arrigan and E. Lojou

### Division 3 – ELECTROCHEMICAL ENERGY CONVERSION AND STORAGE

Experimental and theoretical aspects of electrochemistry in which the goal is the interconversion of energy between different forms or the storage of energy, including the processes themselves and materials used for these purposes.

Chair: S. Passerini, Past Chair: D. Jones, Chair Elect: R. Kostecki, Vice-Chairs: F. Soavi and H. Uchida

### Division 4 – ELECTROCHEMICAL MATERIALS SCIENCE

Aspects of materials science in which electrochemistry is part of the synthesis, processing, surface treatment, corrosion, characterization or modeling of new or existing materials, or in which electrochemistry is the user of such materials.

Chair: Chair: S. Brankovic, Past Chair: M. Ryan, Chair Elect: G. Zangari, Vice-Chairs: N. Birbilis and M. Vorotyntsev

### Division 5 – ELECTROCHEMICAL PROCESS ENGINEERING AND TECHNOLOGY

Experimental and theoretical aspects and applications of electrochemistry in which engineering issues play a significant role, including scale-up and reactor design.

Chair: J. Peralta-Hernandez, Past Chair: F. Lapicque, Chair Elect: K. Bouzek, Vice-Chairs: S. Mitsushima and M. Rodrigo

### Division 6 – MOLECULAR ELECTROCHEMISTRY

Structural and mechanistic aspects of electrode processes of inorganic, metallorganic and organic substances; synthetic applications.

Chair: F. Paolucci, Past Chair: M. Goulart, Chair Elect: O. Buriez, Vice-Chairs: C. Frontana and G. Xu

### Division 7 – PHYSICAL ELECTROCHEMISTRY

Experimental, theoretical and computational aspects of electrochemistry, alone or in conjunction with other methods, relevant to interfaces and conductive media; this shall include physicochemical nature, structure and dynamics from the molecular to the macroscopic level.

Chair: A. Russell, Past Chair: M. Eikerling, Chair Elect: A. Gewirth, Vice-Chairs: M. Arenz and Y. Chen

### New Topics Committee

The New Topics Committee identifies interesting and relevant scientific and technological subjects not covered by the ISE Divisions. It has tasks similar to those of a Division, except that it may have several and changing technical priorities.

Chair: P. Unwin, Past Chair: T. Jacob, Chair-Elect: N.J. Tao

## Regional Representatives

Argentina:	A.E. Bolzan	2015-2017	2nd term
Australia-NZealand:	C. Hogan	2015-2017	1st term

## Co-operation with other Societies

---

*ISE is an Associated Organization of IUPAC and has co-operation agreements with:*

- Bioelectrochemical Society (The)
- Chinese Society of Electrochemistry
- Deutsche Gesellschaft für Galvano- und Oberflächentechnik (DGO)
- Electrochemical Division of the Italian Chemical Society
- Electrochemical Society (The)
- Electrochemical Society of Japan
- Electrochemistry and Electroanalytical Division of the Brazilian Chemical Society
- Electrochemistry Group of the French Society of Chemistry
- European Federation of Corrosion
- Fachgruppe Angewandte Elektrochemie der Gesellschaft Deutscher Chemiker  
(Section Applied Electrochemistry of the Society of German Chemists)
- Korean Electrochemical Society
- Mexican Electrochemical Society
- Royal Society of Chemistry (The)
- Sociedad Iberoamericana de Electroquímica
- Society for Electroanalytical Chemistry (The)

---

## ISE Honorary Members

---

Honorary Members are appointed by the Executive Committee, after consultation with the Council, primarily in recognition of their contribution to ISE. The total number at any time is limited to ten.

The first Honorary Member of ISE, appointed in the year 2003, was **Otmar Dossenbach**, Treasurer of the Society for 21 years (1980-2000) and Executive Secretary for 2 years (2001-2002).

Two new Honorary Members were appointed in the year 2004: **Roger Parsons** and **Sergio Trasatti**, former Presidents of the Society.

Three Honorary Members were appointed in the year 2005: **Ron Armstrong**, former Editor-in-Chief of *Electrochimica Acta* for 18 years, **Elton Cairns** and **Dieter Landolt**, former Presidents of the Society,

One Honorary Member was appointed in the year 2011: **Sharon Roscoe**, former Secretary General of the Society.

---

## ISE Fellows

---

In recognition of their scientific or technical contributions to electrochemistry, the Society may confer on individual members the distinction of ISE Fellowship. Such ISE Fellows are appointed by the Executive Committee after consultation with the Council. The appointment does not carry with it automatic life-time ISE membership.

The present Fellows of ISE are:

H. Abruña	J. Heinze	Z. Samec
R. Adzic	R. Hillman	R. Savinell
A. Aldaz	B.J. Hwang	E. Savinova
R. Alkire	G. Inzelt	D. Schiffrin
Ph. Alongue	K. Itaya	W. Schmickler
C. Amatore	Y. Ito	P. Schmuki
D. Aurbach	H. Ju	F. Scholz
P. Bartlett	A. Jutand	W. Schuhmann
R. J. Behm	T. Kakiuchi	B. Scrosati
A. Bond	A. Karyakin	A. Shukla
E. Cairns	H. Kim	U. Stimming
A. Chen	M. Koper	S. Sun
C. Comninellis	A. Kornyshev	Z. Tian
R. Compton	C. Lamy	J. Ulstrup
S. Cosnier	O. Lev	P. Unwin
P. Delahay	J. Lipkowski	K. Uosaki
C. Fan	D. Macdonald	C. Vayenas
W.R. Fawcett	D. Mandler	M. Watanabe
J. Feliu	P. Marcus	A. Wieckowski
C. Gabrielli	R.A. Marcus	G. Wilson
E. Gileadi	N. Markovic	M. Winter
H. Girault	J. McBreen	J. Zagal
L. Gorton	R. Nichols	J. Zhang
R. Guidelli	T. Osaka	
P. Hapiot	M. Osawa	

## Society Awards

### Electrochimica Acta Gold Medal

The Electrochimica Acta Gold Medal may be awarded every two years to the person judged to have made the most significant contribution to electrochemistry in recent years.

### Frumkin Memorial Medal

The Frumkin Memorial Medal may be given once every two years. It recognises the outstanding contribution of a living individual over his/her life in the field of fundamental electrochemistry.

### Prix Jacques Tacussel

The Prix Jacques Tacussel may be awarded every two years to a person who has made important contributions to an electrochemical technique.

### Katsumi Niki Prize for Bioelectrochemistry

The Katsumi Niki Prize for Bioelectrochemistry may be awarded every two years to a scientist who has made an important contribution to the field of bioelectrochemistry.

### Bioelectrochemistry Prize of ISE Division 2

The Bioelectrochemistry Prize of ISE Division 2 may be awarded every two years to a scientist who has made an important contribution to the field of bioelectrochemistry.

### Brian Conway Prize for Physical Electrochemistry

The Brian Conway Prize for Physical Electrochemistry may be awarded every two years, in recognition of the most successful achievements in Physical Electrochemistry in recent years.

### Alexander Kuznetsov Prize for Theoretical Electrochemistry

The Kuznetsov Prize is awarded every two years to a living individual who has made groundbreaking contribution to the theory of electrochemical phenomena.

### Jaroslav Heyrovsky Prize for Molecular Electrochemistry

The Jaroslav Heyrovsky Prize for Molecular Electrochemistry, supported by ISE Division 6, may be awarded annually to a scientist who has made an important contribution to the field of molecular electrochemistry in the last 5 years.

### Tajima Prize

The Tajima Prize recognises the contributions made by younger electrochemists. Candidates must be less than 40 years old. An award may be made every year. The decision of the Award Committee will be based on published work.

### Hans-Jürgen Engell Prize

The Hans-Jürgen Engell Prize may be awarded annually to a young electrochemist on the basis of published work in the field of corrosion, electrodeposition or surface treatment.

### Oronzio and Niccolò De Nora Foundation Young Author Prize

The Oronzio and Niccolò De Nora Foundation Young Author Prize may be awarded annually to a scientist of less than 30 years for the best paper published in the ISE society journal in the calendar year preceding the award.

### ISE Prize for Environmental Electrochemistry

The ISE Prize for Environmental Electrochemistry may be awarded annually to a scientist of less than 35 years of age on January 1 of the year of the award, for recent application-oriented achievements in the field of environmental electrochemistry.

### ISE Prize for Applied Electrochemistry

The ISE Prize for Applied Electrochemistry may be awarded annually to a scientist of less than 35 years of age on January 1 of the year of the award, for recent achievements in the field of applied electrochemistry.

### Early Career Analytical Electrochemistry Prize of Division 1

The Early Career Analytical Electrochemistry Prize of ISE Division 1, sponsored by OrigaLys, may be awarded annually to a scientist of less than 35 years of age on January 1st of the year of the award in recognition of her/his recent achievements in Analytical Electrochemistry.

### Electrochimica Acta and ISE Travel Award for Young Electrochemists

The Electrochimica Acta Travel Awards for Young Electrochemists are aimed at favouring the participation of young electrochemists in the ISE Annual Meetings. The applicants must be ISE members. They must have obtained their Ph.D. not earlier than 6 years before the deadline for applications.

---

## ISE Sponsored Meeting Information

---

### What is an ISE sponsored meeting?

You may have noticed that scientific meetings in the field of electrochemistry are often labelled “ISE sponsored Meeting”. What does this mean? In addition to organizing its own meetings, such as the Annual and Topical Meetings, ISE may sponsor other international scientific meetings in the area of electrochemistry. ISE sponsorship is intended to be a sign of quality for the meeting.

### What are the requirements for ISE sponsorship?

ISE requires that the scientific quality of the meeting reaches the standard of its own meetings. It is desirable that the advisory board consists of ISE members, as far as possible. The meeting must be open to all ISE members.

### Who decides?

The decision is normally taken by the officers of the ISE Division in whose field of interest the topic of the meeting lies. ISE Division Officers should be involved in the organisation of the meeting. The ISE Executive Committee decides on the sponsorship for meetings of general interest.

### What are the obligations of the organizers?

The organizers have to publicise the ISE sponsorship in all the official documents related to the meeting (announcements, program, website etc.). At the meeting, a representative of ISE must be allowed to say a few words on behalf of the Society, and ISE must have the opportunity to advertise. After the meeting, the organizers should submit a short report to ISE to be published on the ISE website.

### What do the organizers receive from ISE?

ISE publishes announcements and reports of ISE sponsored meetings on its website. The ISE Office can organize, free of charge, mailings to all, or a group of ISE members. In appropriate cases, there may be a special issue of *Electrochimica Acta* associated with these meetings. Decisions about special issues are made by the Editor-in-Chief.

### What about money?

ISE sponsorship of a meeting does not necessarily include a financial contribution from ISE. The sponsoring Division(s) may use its funds to support such a meeting. The level of financial contribution will be determined by the Division(s), but a typical sum may be 500 Euros.

### How to apply for ISE sponsorship?

If you would like to have the scientific meeting you are organizing sponsored by ISE, please send an e-mail to the ISE Office, at least one year in advance of the time of the meeting, and attach a completely filled in sponsor request form. This form can be found on the ISE website at: <http://ise-online.org/sponsmeet/info.php>. The decision will be taken by the Officers of the sponsoring Division(s), or by the Executive Committee, and the ISE Office will inform the applicant.

---

## ISE Regional Student Meetings

---

Graduate Students who are members of ISE and intend to organize a Regional Student Meeting can apply for ISE financial support. Applications submitted by Graduate Students jointly with their supervisors or with other senior members of the staff of their university are also acceptable, but it is expected that the students will be engaged in the organizational aspects of the meeting as much as possible. Regional Student Meetings are typically one-day meetings involving graduate students active in the geographic area where the meeting takes place. The format of the meeting (oral presentations, posters, discussion sessions, other) is autonomously decided by the organizers who will be responsible for securing a venue and collecting registrations. No registration fee should be requested, if financially possible. When the Regional Student Meeting is associated to a larger ISE-sponsored meeting taking place in the same venue, the application must provide clear indication on the connections between the two events and must clearly describe the independent activities reserved to student participants. No later than one month after the meeting, the organizer(s) will send to the ISE Office a report on the event, including the names and the e-mail addresses of the participants. The student participants will be invited to apply for ISE membership. A report giving an overview of the meeting, accompanied by suitable pictures if available, will be posted on the ISE website under Student Activities.

Applications for ISE support must be sent by e-mail to the ISE Office, with a copy to the Regional Representative of the country where the meeting is organized, 3-12 months before the meeting date, using the application form. The local ISE Regional Representative, if requested, will assist the potential meeting organizer in the preparation of the application. Applications will be analyzed by a committee consisting of (i) ISE Immediate Past President (ii) ISE Secretary General, (iii) ISE Treasurer, (iv) ISE Vice President responsible for Educational Activity and (v) ISE Vice President responsible for Regional Sections. The response will be communicated to the applicant and to the relevant Regional Representative no later than 1 month after the application submission.

The maximum financial support will be 600 €; the expected use of the funds must be specified in the application. Co-sponsoring by other Societies and/or institutions is possible.

# PalmSens<sup>3</sup>

Potentiostat / Galvanostat / Impedance Analyzer

- ✓  $\pm 5.000$  V dc-potential range
- ✓  $\pm 8.0$  V compliance voltage
- ✓ current ranges from pA up to 10 mA (8 ranges)
- ✓ frequency range of 100  $\mu$ Hz to 50 kHz
- ✓ ac- amplitude range of 1 mV to 0.3 V (rms)

## **Novel Materials for Renewable Energy**

Hongjie Dai  
*Stanford University, USA*

This talk will review our recent work on advancing new types of electrocatalysts and batteries for renewable energy applications. I will talk about achieving high performance electrocatalysts for water splitting including HER and OER. We have developed a novel Ni/NiO heterostructured hydrogen evolution reaction (HER) catalyst with near zero overpotential. The nanoscale nickel oxide/nickel NiO/Ni hetero-structures formed on carbon nanotube sidewalls are highly effective electrocatalysts for hydrogen evolution reaction with activity similar to Pt with near zero overpotential in HER onset in basic solutions. A novel approach to stabilize the catalyst will be presented. We have also developed a NiFe layered double hydroxide (NiFe LDH) oxygen evolution reaction (OER) catalyst with  $\sim 250\text{mV}$  overpotential, which was among the most active OER catalyst in basic solutions. The NiFe LDH exhibited higher OER catalytic activity and stability than commercial Ir based catalysts. Using the highly active Ni/NiO HER and NiFe LDH catalyst, we achieved water splitting using low voltages  $< 1.5$  volt, making it possible to make an electrolyzer for hydrogen and oxygen gas generation running on a single AAA alkaline battery cell. Lastly, I will present our latest development of rechargeable Al ion battery. The past, present and future of Al ion batteries will be discussed.

# Nanomaterials for Energy Conversion and Storage: Structure Design and In-Situ Monitoring

Li-Jun Wan

*Institute of Chemistry, Chinese Academy of Sciences (CAS), Beijing 100190, P.R. China*

e-mail: wanlijun@iccas.ac.cn

With the increasing demand for efficient and economic energy conversion and storage, advanced solar cells, fuel cells, rechargeable batteries with high efficiency have attracted more and more attention. Nanostructured materials are currently of interest for such devices because of their high surface area, novel size effects, significantly enhanced performance, and so on.<sup>1</sup> Here, we reports our recent progress of nanostructure designs for advanced electrode materials as well as in-situ monitoring techniques of electrode/electrolyte interfaces in these systems,<sup>2,3</sup> including the following aspects.

(i) Nanostructured electrocatalysts for fuel cells: To lower the cost of Pt catalysts, various Pt nanostructures and binary catalysts have been proposed.<sup>4</sup> Hanging Pt hollow nanocrystal assemblies on graphene could further improve the electrocatalytic performance of Pt nanocatalysts.<sup>5</sup>

(ii) Nano/micro hierarchical electrode materials for Li-ion & Li-S batteries: The performances of lithium batteries are hindered by the specific capacities and kinetics of electrode materials.<sup>1,2</sup> Hierarchically nano/micro-structured anode and cathode materials with improved electrochemical performance have been designed and synthesized.<sup>6</sup> Nanocarbon networks are suggested to be good solutions for promoting the kinetics of electrode materials used in Li-ion and Li-S batteries.<sup>2,7,8</sup> To address the surface/interface issue of nanomaterials, we also discuss carbon and carbon-free nanocoatings for nanostructured electrode materials.<sup>9,10</sup>

(iii) In-situ monitor: Reactions taking place on the electrode/electrolyte interface, such as surface film formation accompanied by electrolyte decomposition and deterioration of the host structure of electrode materials, play an important role in the performance and calendar-life characteristics of batteries. Several in-situ monitoring techniques, including in-situ ECSTM, and in-situ ECAFM, have been developed for the direct observation and characterization of the formation of SEI on graphite anode, Si nanowire anode, and  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode during the Li-ion battery operation.<sup>11,12</sup>

Dr. Li-Jun Wan is a Professor at Institute of Chemistry, Chinese Academy of Sciences (ICCAS), Director of CAS key laboratory of molecular nanostructure and nanotechnology, Director of Beijing National Laboratory for Molecular Science, and Chairman of Academic Committee of ICCAS.

Dr. Wan graduated from Dalian University of Technology in 1982, and received his Ph.D from Tohoku University of Japan in 1996. His research focuses on (1) the study of single molecule, molecular reaction and molecular assembly on solid surface by chemical environment and electrochemical scanning probe microscopy, and (2) nanomaterials and their applications in energy conversion/storage and environmental protection such as for Li-ion battery, fuel cell, solar cell, and water processing. He published more than 300 peer-reviewed papers in the journals including Nat. Comm., PNAS, JACS, Angew. Chem., and Adv. Mater. He serves as Members of Editorial Board and International Editorial Advisory Board such as Science China Chemistry, JACS, Acc. Chem. Res., Angew. Chem., ChemComm., Adv. Mater., and Associate Editor of JACS. His main awards include: Chemistry Award, TWAS (the Academy of Sciences for the Developing World); 2<sup>nd</sup>-Class National Natural Science Award, China; Natural Science Award, Beijing and Prize for Scientific and Technological Progress by The HO LEUNG HO LEE Foundation. He is an elected member of CAS, Fellow of TWAS, Fellow of Royal Chemical Society. He is elected as Vice-President of Chinese Chemical Society and President of Chinese Society of Electrochemistry.

# Electrochemical Imaging with Micro/Nanoelectrode Systems

Tomokazu Matsue

*WPI-Advanced Institute for Materials Research (WPI-AIMR), Tohoku University  
Aramaki 6-6-11-605, Aoba, Sendai 980-8579, Japan  
[matsue@bioinfo.che.tohoku.ac.jp](mailto:matsue@bioinfo.che.tohoku.ac.jp)*

Electrochemical imaging is not popular as compared with conventional imaging methods based on optical measurements. Since there have been increasing demands for visualization of local electrochemical phenomena, several imaging technologies based on electrochemical measurements have been proposed so far. There are two basic ways to realize electrochemistry-based imaging [1]. One is to use a scanning probe to pick up localized electrochemical reaction to visualize the surfaces. The other is imaging based on microelectrode arrays to obtain multi-point electrochemical signals to give images.

The most frequently-used tool in the former category is a scanning electrochemical microscope (SECM) [2] and related systems. SECM equips a micro/nanoelectrode scanning probe to acquire information on electrochemical property of surfaces without physical contact. The distance control between the probe and sample has been a big challenge to improve the temporal resolution and sensitivity. We have incorporated an ion-conductance feedback control in SECM system (SECM-SICM) for simultaneous noncontact imaging of the topography and electrochemical signals [3]. SECM-SICM acquired high-resolution topographic images of live cells together with the map of their electrochemical signals. We also developed voltage-switching mode scanning electrochemical microscopy (VSM-SECM) for high-resolution bioimaging [4]. Recently we modified these systems and combined with a scanning electrochemical cell microscopy (SECCM) to fabricate NanoSECCM. This system was applied to visualize localized electrochemical property of battery materials [5].

Electrochemical imaging can also be realized by using microelectrode arrays. The conventional array consists of an array of electrodes with the same number of corresponding bonding pads. This method is easy to implement from a technological point of view; however, the number of individually addressable electrodes is limited since sufficient space for bond pads is not available in surrounding areas. To solve this problem, we developed a novel devices based on electrochemical measurements of redox cycling (LRC) [6]. The LRC was induced on a planar device with row and column electrodes [7]. The crossing points of the row and column electrodes served as the measurements points with limited number of bonding pads for external connection. The LRC devices with microwells at individual measurement points were applied for imaging of gene expression from single cells and high-throughput detection of differentiation of embryonic stem cells [8]. A CMOS-based Bio-LSI with an array of microelectrodes was also fabricated for rapid, highly-sensitive, comprehensive analysis and imaging of biomaterials [9].

# Neglected, Forgotten or Unimportant? Inactive Materials in Lithium Ion Batteries

D. Gallus, R. Wagner, M. Amereller, J. Kasnatscheew, E. Kraemer, S. Krueger, X. Qi, J. Li,  
I. Cekic-Laskovic, and M. Winter

*MEET Battery Research Center, Institute of Physical Chemistry, University of Muenster, Corrensstraße 46, DE-48149 Münster, Germany*

*Helmholtz Institute Muenster (HI MS) 'Ionics in Energy Storage'*

*E-mail: [martin.winter@uni-muenster.de](mailto:martin.winter@uni-muenster.de); [m.winter@fz-juelich.de](mailto:m.winter@fz-juelich.de)*

Today, it is widely accepted that materials research in the field of electrochemical energy storage has to follow a system approach as the interactions between active materials, the electrolyte, the separator, and the various inactive materials are of similar or even higher importance as the properties and performance parameters of the individual materials only. Surprisingly, apart from a more recent interest in electrolytes, still inactive materials are considered as commodity within the scientific community and the important influence of the interactions between anode and cathode is mostly neglected.

In this presentation, we will discuss the influence of so-called 'inactive' materials on the performance of lithium ion batteries. Apart from electrolyte considerations, we will discuss (i) the so-called Al current collector corrosion, which is actually an anodic dissolution reaction of the non-noble metal aluminum [1,2], (ii) the influence of the conductive filler on lithium ion battery performance [3,4], and (iii) how reactions at the anode deteriorate the cathode performance [5].

# **A Voltammetric Odyssey: From Homogeneous Dropping Mercury to Heterogeneous Macro and Nano Electrodes; From the Manual Era to Advanced Automated High Speed Computation**

Alan M. Bond

*School of Chemistry, Monash University, Clayton Vic 3800, Australia  
alan.bond@monash.edu*

At the start of my career as an electrochemist, the technique of polarography, using a dropping mercury electrode, dominated the field of voltammetry. As an apprentice, I learned how to measure current that oscillated with the growth and fall of the mercury drop using a galvanometer, apply potential with a rheostat/potentiometer and point by point construct and analyse current -potential- time curves. At that time, almost all aspects of the voltammetric experiment involved a manual manipulation of some kind. In contrast, some 40 years later, the dropping mercury electrode is essentially obsolete due to occupational health concerns (rational?). In its place, a plethora of electrode materials are now available that are often heterogeneous in nature and range in size from discs of cm diameter down to the nanometre dimension and high speed computers govern most aspects of now highly automated instrumentation and data analysis.

So what have I achieved and observed in my career? During my voltammetric odyssey, with inspiration and help from co-workers, I undertook my PhD studies on vacuum lines with Teflon dropping mercury electrode and used a Tesler coil to create dropping mercury electrode made from Kel-F. These non-glass materials allowed polarographic studies to be made in anhydrous HF and the reduction of metal fluorides to be achieved for the first time. This was followed by a substantial period of interest in microelectrodes made in numerous shapes from organometallic paints and in disc form by use of Wollaston wire and skilled glassblowing. Near steady state studies with and without added supporting electrolyte and other advances were implemented with the microelectrodes. The use of AC methods in my laboratories commenced with simple superimposition of a sinewave onto the DC waveform used in classical voltammetry. Now sophisticated forms of Fourier transform aided methodology, combined with advanced forms of data analysis are routine and evolution from “log plot” analysis of data to advanced data optimisation methods using high speed computers has occurred. Instrumentation has also developed spectacularly. My career has bridged the manual analogue to digital era. The latter has progressed from a laboratory computer to the early microprocessors with 2K memory and hand assembled programming and now to parallel processing with an array of computers that are part of recent developments in our version of large amplitude Fourier Transformed AC voltammetry. Of course the theory can now accommodate many nuances that were impossible to implement at the start of my career. Nowadays, it can be anticipated that most reasonable mechanisms can be simulated using commercially available software packages.

In this lecture, a voltammetric odyssey will be presented from my perspective. There are many aspects of the present day “modus operandi” that are revolutionary, but in some ways it is difficult to understand why the best electrode for theory-experiment comparisons, the dropping microelectrode, is now confined to a vague memory. I will conclude by noting that use of this electrode might well enable far deeper understanding to be made on the nature of double layer and mass transport in ionic liquids than has emerged from studies with theory-experiment comparisons using modern electrodes. This is an area where theory may have outstripped experiments and where obtaining high quality fundamentally important data with heterogeneous electrode has proved to be problematic?

The above represents the past and the present, but what about the future? The lecture will conclude with crystal ball gazing as to voltammetric advances that might be introduced in the next decade. Of course I also acknowledge with pleasure the contributions from many outstanding electrochemists with whom I have collaborated during my career. It is fellow electrochemists who have consolidated some of my crazy ideas into reality and provided much of the inspiration that has made my award of the 2014 ISE Electrochimica Acta Gold Medal possible.

# The Investigation of Passivity of Metals Studied by Surface Analytical Methods, a Review

Hans-Henning Strehblow

Heinrich-Heine-Universitaet-Duesseldorf

Universitaetsstr. 01, D-40225 Duesseldorf

[henning@uni-duesseldorf.de](mailto:henning@uni-duesseldorf.de), [hstrehblow@gmail.com](mailto:hstrehblow@gmail.com)

The passivity of metals has been studied since more than 200 years with chemical and electrochemical methods. When commercial Ultra High Vacuum systems were available with an efficient specimen transfer in the mid-seventies, X-ray Photoelectron Spectroscopy (XPS) and Ion Scattering Spectroscopy (ISS and RBS) were applied to study the chemistry of passive layers. A specimen transfer without contact to the laboratory atmosphere excluded the contamination of the surface and uncontrolled oxide growth. Later the development of Scanning Methods (STM, SFM) and Synchrotron Methods (XAS and XRD) allowed a reliable *in situ* investigation of the atomic structure of these surface films. The chemical and structural changes could be investigated with a systematical variation of the environmental parameters like the electrode potential, the composition of the solution and metal, as well as the changes with time from the millisecond range up to hours or days. In this lecture an overview of the achievements of these methods and the results for several metals and their alloys are given as examples.

Passivity of metals is determined by thermodynamic and kinetic parameters, which involves the chemical properties of the metals and their oxides and hydroxides as well as the influence of the electrolyte. Passivating oxide films have usually a complicated multilayer structure with the lower valent cations inside and the higher valent cations outside. The duplex passive films on copper or iron substrates are good examples. For alloys more noble components remain at the metal/oxide interface whereas the reactive components form the oxide layer like in the case of aluminum with a small copper content as can be shown by RBS depth profiles. If both components are reactive, both are present within the oxide, but one of them is often seriously enriched like for Cr-Fe or Cr-Ni alloys. Here the extremely slow dissolution kinetics of  $\text{Cr}^{3+}$ -ions at the oxide/electrolyte interface are the cause for their enrichment within the passive layer in acidic electrolytes, which easily can be shown by XPS and ISS depth profiles. In alkaline solutions Fe(III)oxide remains at the outer surface due to its small solubility for high pH values. The slow dissolution- and reaction-kinetics of  $\text{Cr}^{3+}$  within an oxide- or a chloride-matrix are also the cause for the excellent resistance of pure Cr to halide attack or its beneficial addition to other metals to withstand pitting by halides.

The atomic structure of the passive layers may be visualized directly by STM. Usually a film gets more protective with aging which goes along with the development of a crystalline structure. Often there exists an epitaxial relationship between the oxide film and the metal substrate and the details of the changes of the metal surface are ruled by its orientation, as can be seen by the anodic oxidation of copper for different crystal orientations. Detailed changes may be followed by *in situ* STM with time for small driving forces, i.e. only a small overpotential for oxide formation. Similarly the reduction of an oxide layer can be studied with time resolution. For Co (0001) surfaces this has been examined with various intermediate structures of  $\text{Co}(\text{OH})_2$  species moving on the metal surface and their final integration as Co atoms into the metal terrace with a decoration of its steps by  $\text{Co}(\text{OH})_2$  trimers. In situ XAS studies of metal oxidation and reduction allows even the determination of the near range order of disordered or amorphous oxide films. Investigations have been performed of Cu deposits on Pt clusters by XAS in transmission. The investigation of oxide growth on bulk metals requires a grazing incidence geometry with angles below total reflection of the X-ray beam for a sufficient suppression of the contribution of the substrate metal to the XAS signal. Examples for silver oxide formation on Ag are presented with  $\text{Ag}_2\text{O}$ - and AgO-formation according to the applied electrode potential. Dissolving species in front of an electrode in solution may be investigated by XAS in transmission with the X-ray beam passing close to the metal surface.

Electrochemical Double Layer Capacitors (EDLCs), so called supercapacitors, are now used in a large variety of applications, such as start & stop modules in cars. In these devices organic solvents are often used that may present some hazard for the users. Thus, alternative electrolytes such as room temperature ionic liquids (RTILs) have been envisioned. In micro-supercapacitors ( $\mu$ SCs), the use of liquid electrolytes is prohibited since there might be some leakage. Additionally,  $\mu$ SCs need to be implemented in microelectronic circuits which are often designed using a reflow soldering process, i.e. an annealing at 250°C for few tens of seconds. Thus, the use of volatile solvents is forbidden. RTILs have a fair ionic conductivity and a broad temperature operating range, without flammability. They can also be confined in a host matrices, which prevents from leakage, in which their liquid state properties are maintained. Such ionogel,<sup>1</sup> could enable to increase the safety of energy storage devices such as EDLCs. Furthermore, ionogels for which host network is made solely of mesoporous silica can solve the thermal stability issue when reflow soldering process is used.

In this communication, we will evidence the interest of ionogel electrolytes in various EDLCs designs, namely standard EDLCs using two symmetric high loading activated carbon electrodes<sup>2</sup> (Fig. 1), and microsupercapacitors using silicon nanowires/nanotrees electrodes. The electrochemical performance (energy and power densities, long term cycling, temperature behavior) will be compared to that of their liquid based equivalent and some perspectives will be given for future devices.

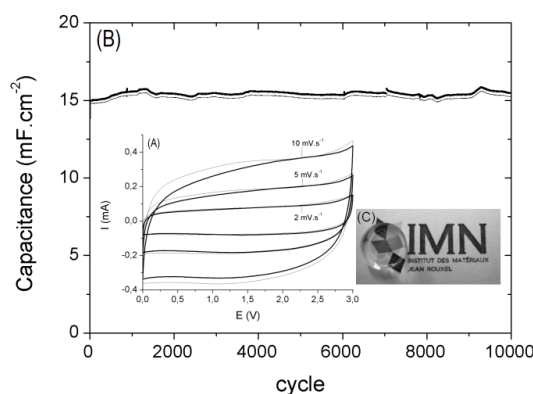

Fig.1 : (A) CVs (0 to 3V) at 2, 5 and 10mV.s<sup>-1</sup> of activated carbon based EDLCs using ionogel (—) and RTIL (---) electrolytes. (B) Long term cycling behaviour of EDLC with Ionogel electrolyte : charge(—) and discharge (---) capacitances obtained with CCGC (I=1mA.cm<sup>-2</sup>). (C) 1 cm Ø transparent ionogel.

In our society Li ion batteries are widely used. Intensive research is conducted on next generation batteries such as metal-air batteries. The requirements of high energy density dictate the use of very high (oxidizing) or very low (reducing) potential. These extreme potentials can cause molecular compounds to undergo electron transfer reactions at the interfaces. This is well documented for lithium-ion batteries, where a solid electrolyte interphase (SEI) between the lithiated graphite electrode and the electrolyte is formed by the decomposition of electrolyte components mainly during the first charging process. This layer is critical for the performance and safety of the Li ion batteries [1]. This talk will review a number of approaches to understand charge transport across SEI by using concepts of microelectrochemistry in particular scanning electrochemical microscopy (SECM).

Characterization of the SEI is a challenge, because of the variety of chemically similar components and enclosed electrolyte species. Furthermore, *ex situ* analysis of the SEI requires separation and isolation of the SEI, which may change the content and the structure of the SEI [2]. Recently we used the feedback mode of scanning electrochemical microscopy (SECM) to investigate *in situ* the electron transport at the lithiated graphite (Figure) [3]. 2,5-di-*tert*-butyl-1,4-dimethoxy benzene was identified as an useful SECM mediator providing sufficient stability and sensitivity to study passivation properties of SEI. All measurements were conducted under open circuit conditions. The SECM results show gradual and significant short-term *spatiotemporal* changes of the SEI properties and demonstrate the dynamic and spontaneous behavior of SEI formation, damage and reformation under open circuit conditions above lithiated graphite anodes. The results emphasize that *spatiotemporal* changes of the passivating SEI properties are highly localized and occur preferentially in between the gaps of graphite particles. Significant short-term *spatiotemporal* changes of the SEI properties clarify that electrolyte reduction still occurs after SEI formation at localized spots.

Using a related setup for the investigation of lithium-air batteries, gas permeation through a gas-diffusion electrode (GDE) into a Li<sup>+</sup>-containing electrolyte has been studied in order to understand pore blocking vs. electrode coating by lithium oxides during the operation of lithium-air batteries [4]. The GDE was positioned between an Ar-O<sub>2</sub> and an Ar atmosphere. The passivation of the local detector electrode was avoided by the use of a pulse program that contained a cleaning step for the microelectrode. The difference in O<sub>2</sub> partial pressure was the driving force for the transport of O<sub>2</sub> through the wetted pore structure of the GDE. Depending on the potential of the GDE, O<sub>2</sub> enters the organic electrolyte or is completely consumed in the GDE. In this way it was possible to detect the build up of concentration gradients in the electrolyte above an GDE in organic electrolytes in dependence of the operation characteristics of the air cathode. Intermediates of the oxygen electrode have been detected but the chemical identification of such short lived intermediates remains challenging.

The electrochemical performance of carbon film electrodes can be widely controlled depending upon surface termination or doping of other atoms such as oxygen, nitrogen, fluorine and various metals. We have been studying nanocarbon film electrodes formed by various sputtering techniques<sup>1,2</sup>. The surfaces of the carbon films are electrochemically or plasma treated to introduce oxygen and fluorine containing groups on to the surfaces. As we reported previously, electrochemically treated carbon film becomes hydrophilic by significant increase in the surface oxygen concentration<sup>3</sup>. This hydrophilic and very flat surface of the carbon film is advantageous to measure relatively large biomolecules such as oligonucleotides. The carbon film can detect the amount of all the bases in the single stranded DNA and successfully demonstrated SNPs and DNA methylation analysis<sup>4,5</sup> because the adsorption of biomolecules can be significantly suppressed.

A nitrogen-doped nanocarbon film electrodes with mixed sp<sup>2</sup> and sp<sup>3</sup> bonds formed using ECR sputtering method has a very smooth surface with an average roughness of 0.1 to 0.2 nm, which is almost independent of nitrogen concentration<sup>6</sup>. The oxygen and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) reduction potentials at N-ECR carbon film electrode shifted about 0.3 and 0.15 V (vs. Ag/AgCl), respectively, and the peak height of H<sub>2</sub>O<sub>2</sub> is greatly increased similar to well known carbon alloy materials<sup>8</sup>.

We previously reported electrochemically stable fluorinated nanocarbon film by CF<sub>4</sub> plasma treatment that had an sp<sup>2</sup> and sp<sup>3</sup> hybrid bonds<sup>9</sup>. The contact angle of the film surface increased from 72 to 93 degree after surface fluorination. We employed the fluorinated carbon film electrode to selectively detect hydrophobic antioxidants in foods and drinks. The film electrode shows fast electron transfer for hydrophobic  $\alpha$ -tocopherol. In contrast, electrochemical responses for hydrophilic antioxidants such as ascorbic acid were effectively suppressed at the fluorinated film electrode<sup>10</sup>. These properties allowed us to achieve selective and quantitative measurements of hydrophobic antioxidants with maintaining the suppression for the responses of hydrophilic antioxidants in the analyte solution. The fluorinated nanocarbon film was also applied for selective electrochemical reaction of ferrocene against Fe<sup>2+</sup>/Fe<sup>3+</sup> redox couple, which could be applied electrochemical amplification of electrochemical biosensor for lipopolysaccharide (LPS).

Metal nanoparticles embedded carbon film electrode was developed by co-sputtering of metal and carbon because of low intermiscibility between metals and carbon. The Pt nanoparticles dispersed carbon electrodes can be applied for stable detection of hydrogen peroxide<sup>11</sup>. We formed Pt nanoparticles embedded carbon film on the surface of porous Teflon film and successfully applied for continuous monitoring of HCl and HBr gas. More recently, we fabricated Ni/Cu nanoalloys embedded carbon film electrode using unbalanced magnetron (UBM) co-sputtering of Ni, Cu and carbon. The improved sensitivity and repeatability was realized for detecting clinical sugar markers such as D-manitol by high electrocatalytic activity of Ni/Cu nanoalloy compared with bulk metal electrodes.

# From Protein Film Bioelectrochemistry to Biomedical Devices and Diagnostics

James F. Rusling,<sup>†,‡,§,∅</sup>

<sup>†</sup>*Department of Chemistry, 55 North Eagleville Road, Storrs, Connecticut 06269*, <sup>‡</sup>*Institute of Materials Science, University of Connecticut, Storrs, Connecticut 06269*, <sup>§</sup>*Department of Cell Biology, University of Connecticut Health Center, Farmington, Connecticut 06032*

<sup>∅</sup>*School of Chemistry, National University of Ireland at Galway, Ireland*  
[James.Rusling@uconn.edu](mailto:James.Rusling@uconn.edu)

My electrochemical career began at Wyeth Labs in Philadelphia in the 1970s and continued in Prof. Petr Zuman's lab. In the early 1990s, Dr. Ala Nassar and I began to develop protein film voltammetry for direct electron transfer involving heme enzymes like cyt P450s in thin lipid films. Dr. Yuri Lvov later joined our group as a senior scientist and with Prof. John Schenkman at our health center we began to work on cyt P450s and their enzyme reactions in thin layer-by-layer (LbL) polyelectrolyte films, which were much more stable and ultrathin. We demonstrated electrochemically driven enzyme activities of human cyt P450s the same or better than the NADPH-activated enzyme system in solution. With Dr. Sadagopan Krishnan, we later developed the first electrochemically-driven cyt P450 films that followed the natural redox cycle by using cyt P450s in film of polyelectrolytes and microsomal cyt P450 reductase. We also showed that voltammetry could reveal mechanistic details of cyt P450-reductase interactions.

These bioelectrochemistry efforts eventually led to applications to toxicity screening. The link is that cyt P450s and other metabolic enzymes often make toxic metabolites that react with DNA and these metabolites are known as genotoxic species. Schenkman and I and our students developed arrays combining DNA, a Ru-dye polymer and metabolic enzymes using LbL technology in which increased levels of electrochemiluminescence (ECL) for damaged DNA, and thus were able to measure relative rates of DNA damage from a metabolized chemical. Our most advanced version is a microfluidic array that performs cell-free in vitro metabolic genotoxicity screening of pollutants and drugs using enzymes from four different organs. We also developed analogous high-throughput approaches to assessing metabolite-related DNA damage using LC-MS/MS to complement the electrochemical arrays.

Our expertise in film fabrication on electrodes coupled with the nanomaterials skills of Prof. Fotios Papadimitrakopoulos led to projects in microfluidic immunoarray development for protein-based cancer diagnostics. We found that nanostructured sensor arrays coupled with microfluidics and massively multilabeled particles for detection provide very high sensitivity for multiple proteins using amperometric and electrochemiluminescent (ECL) detection. We recently automated one of these approaches, and are working on additional automated immunoarrays based on 3D printing.

# Nano Impacts: Recent Advances

Richard G Compton

*Richard.compton@chem.ox.ac.uk*

Recent progress in the electrochemical study of single nanoparticles by means of the nano-impacts approach will be surveyed and evaluated

The design of electrodes and nano-impacts methodology allowing the electrochemical sizing of nanoparticles as small as 4nm will be described, and shown to be applicable to nanoparticle concentrations as low as 0.1 pM.

Contrasts will be drawn between experiments conducted on ensembles of nanoparticle, as in nanoparticle modified electrodes, and the behavior contrasted seen for single nanoparticle experiments. Important factors include the change of mass transport regime, altered apparent electrochemical reversibility and the incomplete 'stripping' seen for aggregated nanoparticles.

The role of surface charge on the observed electrochemical behavior will be explored with reference to experiments carried out using indigo nanoparticles in weakly supported aqueous electrolytes.

Experiments with diverse types of nanoparticles will be reported, namely metallic (Ag, Cu, Ni, Au), metal oxides ( $\text{Fe}_3\text{O}_4$ ), organic (indigo and oil blue) and polymeric (poly-N-vinyl carbazole) as well as studies on single drug encapsulating liposomes.

Electro-catalytic processes occurring during nano-impacts of soft nanoparticles will be discussed with reference to the reduction of oxygen mediated via attomole quantities of vitamin B12 present in single nano-droplets.

Finally a speculative electrochemical perspective on the origins of the toxicity of silver nanoparticles will be offered.

# Molybdenum Enzyme Electrochemistry

Paul V. Bernhardt

*School of Chemistry and Molecular Biosciences,  
University of Queensland, Brisbane 4072, Australia  
p.bernhardt@uq.edu.au*

The mononuclear Mo enzymes comprise a diverse but coherent family of oxidoreductases that typically catalyse coupled two-electron, O-atom transfer reactions and are found in all forms of life. The reductases and oxidases/dehydrogenases are equally represented amongst the mononuclear Mo enzymes *i.e.* eq. 1 may proceed either to the left or right depending on the enzyme.

Like all redox active enzymes, an external electron donor or acceptor is necessary to sustain catalysis. Integration of the Mo enzyme with an electrical circuit is central to the transition from native function to an artificial bioelectronic device. There are two main ways that this can be done: direct electron transfer between the enzyme and the electrode or indirectly *via* mediators that relay electrons between the electrode and the enzyme. Both approaches have their merits and their shortcomings. Above all else, electronic communication with the enzyme must be achieved without compromising stability, reactivity of selectivity.

Some recent results from our lab will be presented where we apply different approaches to these remarkable enzymes in an effort to exploit the high selectivity and reactivity of these interesting systems toward the development of biosensors.

mccreery@ualberta.ca

The molecular junction (MJ) is not generally described as “supramolecular”, but it definitely qualifies, since it consists of molecules bonded covalently in parallel between two conducting contacts. We study “all carbon” molecular junctions made by covalent bonding of aromatic molecules to flat, conducting, sp<sup>2</sup> carbon surfaces, then vapor depositing disordered sp<sup>2</sup> carbon to make a conducting “top contact”. Such MJs can be incorporated into electronic circuit consisting of conventional semiconductor components to realize functions not possible with silicon. Electron transport across 1-20 nm differs fundamentally from that in standard semiconductors and thicker organic films, and often involves quantum mechanical tunneling. When molecular orbitals have suitable energies, field ionization can generate charge carriers, and transport may occur across distances much too long for tunneling. Ultraviolet photoelectron spectroscopy and photocurrent measurements from illuminated molecular junctions permit direct determination of energy levels in molecular junctions, often simultaneously with electronic conduction. Molecular junctions also produce light during current flow, indicating significant “ballistic” transport without inelastic scattering. A potential commercial application of molecular junctions in audio processing will also be described and demonstrated.

# Electrochemistry of Membrane Proteins

Jan Vacek

Department of Medical Chemistry and Biochemistry, Faculty of Medicine and Dentistry, Palacky University, Hnevotinska 3, 775 15 Olomouc, Czech Republic  
e-mail: jan.vacek@upol.cz

Membrane proteins (MPs) are proteins associated with the membranes of a cell or separated organelles. It has been estimated that ~30% of all genes in most genomes encode MPs. For this reason, MPs are interesting target molecules in current biochemical research and hence the search for novel methodologies for studying MPs is important in the investigation of their structure and function. In this contribution, a procedure for measuring the intrinsic electroactivity of MPs using mercury and carbon electrodes is described. MPs were analysed after their (a) solubilisation by non-ionic detergents or selected ionic liquids and/or (b) reconstitution into liposomes. The formed species, solubilized proteins (cf. a) or proteoliposomes (cf. b), were adsorbed onto electrode surfaces and typical anodic and cathodic protein peaks were monitored:

The electrochemical responses reflected the concentration of the studied MPs in the samples and the changes in electrochemical peaks indicate the structural changes in the MPs resulting from ligands binding to them. Na/K ATPase (ubiquitous, sodium/potassium pump), uncoupling proteins (components of mitochondrial membranes), protein f1t103 (bacterial periplasmic protein) and cytochromes c (small heme proteins associated with the inner membrane of the mitochondria) were used as model MPs. The applicability of intrinsic electroactivity measurement for MP research is discussed in general, especially in the context of studying the interactions of MPs with detergents, lipids, solid surfaces and binding ligands such as drugs, toxins and various prooxidant agents.

# How to Understand the Electrochemistry of Battery Materials?

Petr Novák, Peter Bleith, Rosa Robert, Tsuyoshi Sasaki\*, Claire Villevieille

Paul Scherrer Institute, Electrochemistry Laboratory

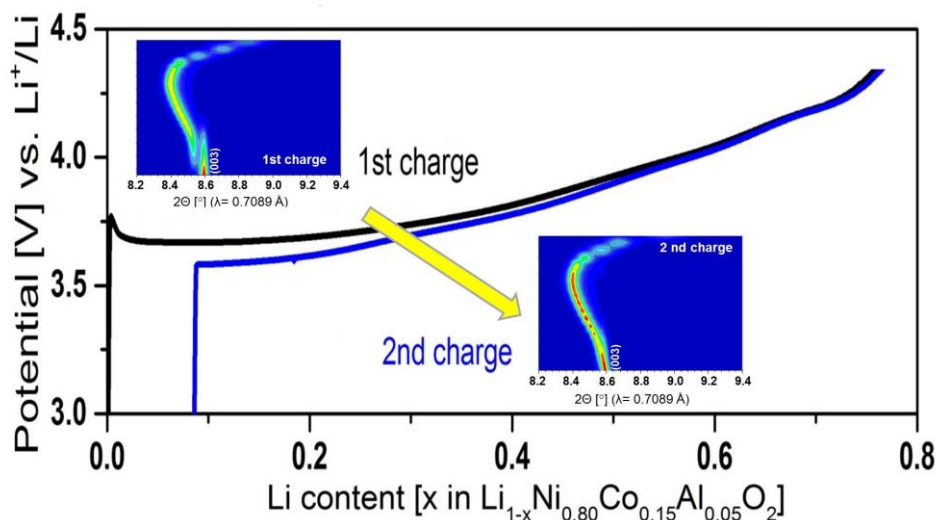

CH-5232 Villigen PSI, Switzerland

\*Toyota Central R&D Labs. Inc., Nagakute, Japan

petr.novak@psi.ch; novakp@ethz.ch

Lithium-ion batteries (LIBs) are now considered to be the most available power sources for portable devices. The next generation of high-end rechargeable batteries will still rely on lithium-ion host materials. Later, post-lithium-ion systems, at first Li/S, are expected to enter the market. But oxides and, more generally, inorganic solid materials reacting reversibly with lithium, will remain the backbone of the future battery systems. Clearly, independently of the technology, understanding the fundamental properties of battery materials and the interactions of these materials with their environment will be the key to further improvements in energy density, safety, and life time of batteries.

In the presentation, focus will be on some interesting effects related to lithium insertion and deinsertion, recently identified in industrially used metal oxide electrodes like NCA,  $\text{Li}(\text{Ni},\text{Co},\text{Al})\text{O}_2$  and LFP,  $\text{LiFePO}_4$ . The data on NCA suggest an unknown irreversible activation of the material in the first electrochemical cycle which seems to be a combination of an irreversible two-phase transition and a reversible solid solution reaction mechanism. Understanding the difference in the reaction pathways that NCA undergoes in the first and subsequent cycles provides further insights into the irreversible charge “loss” between the first charge and discharge. For LFP we found an obvious “memory effect” in the charging curve after a shallow depth of charge and discharge. In contrast to Ni-Cd and Ni-MH batteries, the memory effect of LFP appears already after only one partial cycle. The understanding of the memory effect is highly essential for the exact estimation of the SOC and the effective use of LIBs based on LFP. Additionally, this notable behavior gives us a strong hint to make the real charge/discharge reaction mechanism and kinetics of  $\text{LiFePO}_4$  clear. Moreover,  $\text{LiFePO}_4$  is described to be a phase separating material when cycled under low current density conditions. But *in situ* synchrotron X-ray diffraction under ultra-high rate alternating current and medium rate direct current density excitation revealed a continuous but current-dependent solid-solution regime of  $\text{LiFePO}_4$  and  $\text{FePO}_4$ . In another example, the reaction with lithium of metal titanium oxyphosphates ( $\text{M}_{0.5}\text{TiOPO}_4$ ) will be discussed. These oxyphosphates are a family of isostructural materials exhibiting an unexpectedly high specific charge. The reaction mechanism upon lithiation and delithiation was therefore investigated using a combination of XAS,  $^{31}\text{P}$ -NMR, XRD, EDX, and electrochemical techniques. Surprisingly, the oxyphosphate materials react, through several steps, via a combination of insertion and conversion processes, the reaction mechanism being dependent on the (transition) metal in the structure.

Contour plots of the intensity, at selected  $2\theta$  regions, and corresponding galvanostatic plot for synchrotron data for the first and second charge of NCA to  $4.3 \text{ V Li}^+/\text{Li}$ .

# Supramolecular Enantioselective Recognition at Mesoporous Chiral Metal Surfaces

kuhn@enscbp.fr

Chirality is widespread in natural systems, and reproducing chiral recognition artificially is a major scientific challenge, especially because of the various potential applications ranging from catalysis to sensing and separation science. In this context, molecular imprinting is a well-known approach for generating materials with enantioselective properties, and it has been successfully employed using polymers [1]. However it is particularly difficult to synthesize chiral metal matrices by this method. We report here, for the first time, the elaboration of chiral imprinted mesoporous metal, obtained by the electrochemical reduction of platinum salts in the presence of a liquid crystal phase [2] and chiral template molecules [3]. The porous platinum retains a chiral character after removal of the template molecules. A matrix obtained in this way exhibits a large active surface area due to its mesoporosity, and most importantly also shows a very significant discrimination between two enantiomers, when they are studied using these materials as electrodes in Differential Pulse Voltammetry. Recently it has been possible to extend the concept even to the recognition of enantiomers which are different from the imprinted ones in terms of chemical composition. This is possible due to the geometric nature of the chiral recognition process [4].

Continuous electrochemical flow reactors for efficient conversion of electrical energy into chemicals and vice versa, i.e. fuel cells and electrolyzers, become increasingly important considering energy sustainability and environmental concerns. The electrocatalyst materials, which constitute the core of electrochemical energy conversion devices, however are still a bottleneck for their efficiency. While the optimization of kinetics of electrocatalysts has been widely explored, the highly important stability of the materials is less studied. In this presentation I will demonstrate how fundamental investigations of electrocatalyst stability can be performed online and in parallel to activity determination, and what can be learned from these studies for large scale applications. The focus will be on the recent methodological developments from our group, in particular the scanning flow cell (SFC) coupled to online analytics, which also allows for combinatorial analysis. The potential of this approach will be demonstrated by results on the essential oxygen electrochemistry on noble metal catalysts as used in low-temperature fuel cells and electrolyzers.

To understand the molecular basis of brain functions, researchers would like to be able to quantitatively monitor the levels of neurochemicals in the extracellular fluid in vivo. However, the chemical and physiological complexity of the central nervous system (CNS) presents challenges for the development of these analytical methods. We herein demonstrated a new strategy for in vivo analysis based on bioelectrochemistry by rationally design and careful construction the surface/interface chemistry.

We used the redox nature of neurochemicals at the electrode/electrolyte interface to establish a basis for monitoring specific neurochemicals. Carbon nanotubes provide an electrode/electrolyte interface for the selective oxidation of ascorbate, and we have developed both in vivo voltammetry and an online electrochemical detecting system for continuously monitoring this molecule in the CNS. By using the CNT-based OECS, we compared the dynamic regional changes of extracellular ascorbate level in four different brain regions 1 h after global cerebral ischemia induced by two-vessel occlusion (2-VO). We also compared the change in the level of ascorbate in the different ischemia model (i.e., two-vessel occlusion (2-VO) and left middle cerebral artery occlusion (LMCAO) in striatum. We also demonstrated the validity of the OECS for ascorbate detection as a platform for in vivo evaluation of neuroprotective efficiency of antioxidants by studying the dynamic change of hippocampal ascorbate during the acute period of cerebral ischemia and its responses to intravenous administration of antioxidants including ascorbate and glutathione.

Although  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  are involved in a number of neurochemical signaling processes, they are still difficult to detect in the CNS. These divalent cations can enhance electrocatalytic oxidation of NADH at an electrode modified with toluidine blue O. We used this property to develop online electrochemical detection systems for simultaneous measurements of  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  and for continuous selective monitoring of  $\text{Mg}^{2+}$  in the CNS.

We have also harnessed biological schemes for neurosensing in the brain to design other monitoring systems. By taking advantage of the distinct reaction properties of dopamine (DA), we have developed a nonoxidative mechanism for DA sensing and a system that can potentially be used for continuously sensing of DA release. Using “artificial peroxidase” (Prussian blue) to replace a natural peroxidase (horseradish peroxidase, HRP), our online system can simultaneously detect basal levels of glucose and lactate. By substituting oxidases with dehydrogenases, we have used enzyme-based biosensing schemes to develop a physiologically relevant system for detecting glucose and lactate in rat brain. Because of their unique optical properties and modifiable surfaces, gold nanoparticles (Au-NPs) have provided a platform of colorimetric assay for in vivo cerebral glucose quantification. We designed and modified the surfaces of Au-NPs and then used a sequence of reactions to produce hydroxyl radicals from glucose.

# Alternative PEFC Catalysts for Future Commercial FCVs

Masanori Inaba, Shuhei Yoshino, Masao Shibata, Tatsuya Hatanaka and Yu Morimoto\*

*Toyota Central Research and Development Labs., Inc.*

*41-1 Yokomichi, Nagakute 480-1192 Japan*

*\*Corresponding author email address: [morimoto@mosk.tytlabs.co.jp](mailto:morimoto@mosk.tytlabs.co.jp)*

Toyota Motor Co. has started commercialization of FCV MIRAI to general public In Japan in November, 2014 and will do so in Europe and US in 2015. Although it is an epoch-making accomplishment resulting from long and hard efforts by many scientists and engineers, further development is necessary for wider commercialization. One of the most important technological areas is the electrode catalyst. Pt or Pt based alloys (e.g. Pt-Co for MIRAI) , which is almost exclusively used, can provide sufficient efficiency and power but also poses cost and degradation issues, the latter of which can be avoided by system-based approaches, which, however, cause additional cost issues.

An alternative electrode catalyst is extended thin-film Pt, which was firstly introduced by 3M as NSTF[1], which is totally different from that of the conventional Pt/C electrode: low platinum surface area ( $10 - 25 \text{ cm}^2\text{Pt}/\text{cm}^2$ ), nonconductive substrate, and no ionomer contained. Although NSTF electrodes showed higher efficiency and power density than conventional Pt/C electrodes under suitable operating conditions[2], it has been reported that they tend to show larger performance loss under dry or wet conditions[3].

In this communication, after a short introduction on the present status and challenges on the catalysts, we present our research on thin film electrodes mainly for revealing their general features.

**Figure 1 Pt-coated SiO<sub>2</sub> electrode(left) and its MEA(right)**

Figure 1 shows an ALD-Pt on electrospun SiO<sub>2</sub> fibre electrode and a membrane-electrode-assembly using it for the cathode. The MEA exhibited comparable performance with the conventional Pt/C cell under 80°C, 100%RH condition in spite of the much smaller electrochemical surface area (ECSA), it showed poor performance under overly dry or wet conditions. The overvoltage was analyzed and some countermeasures were examined.

# Heteroatom-Doped Porous Carbon as Electrocatalyst: Surface Properties and Electrocatalytic Activity

Dea-Soo Yang, Min Young Song, Kiran Pal Singh, Fatemeh Razmjooei and Jong-Sung Yu

*Department of Energy Systems Engineering, Daegu Gyeongbuk Institute of Science and technology (DGIST),  
Daegu, 711-873, Republic of Korea, Fax: (+82)53-785-6409, E-mail: [jsyu@dgist.ac.kr](mailto:jsyu@dgist.ac.kr)*

Fuel cells have received a plethora of attention because of their high energy conversion efficiency, low pollution, low operating temperature, high power density, and wide range of applications. Oxygen reduction reaction (ORR) takes place usually on Pt or Pt alloys loaded on carbon support, but their large-scale commercial application has been precluded mainly by the high cost and low durability of the requisite noble metal electrocatalyst [1]. Heteroatom-doped carbon catalysts, due to their high stability, excellent electrocatalytic performance, and economic viability over costly Pt-based catalysts are being pioneered as a suitable alternative [2,3]. Heteroatoms such as N, P and S are most common elements doped into carbon framework for electrochemical reactions.

Although the heteroatom-doped porous carbon materials have evolved as one of best possible solutions in this regard, the probable synergy of heteroatom doping and textural properties has not been well investigated yet in details. Active species, conductivity, porous structure and surface area are the key factors affecting overall electrocatalytic activity of carbon-based electrocatalysts [4]. In this work, we report a noble technique to synthesize highly conductive and microporous N and S-doped carbon from polyaniline (PANI) via a simple hydrothermal method followed by carbonization in presence of iodine. Iodine treatment removes large amount of attached oxygen and other heteroatoms, and as a consequence increases the carbon content. Therefore, the iodine treatment decreases catalytically active heteroatom doping level, which is unfavorable for oxygen reduction reaction (ORR), but at the same time, significantly increases the electrical conductivity, which is beneficial for ORR [5]. In particular, iodine-treated carbonized PANI (CPANI) shows exceptionally high conductivity, about 3 times that of untreated CPANI. Iodine treatment is also found to enhance the micropore surface area of the PANI during carbonization without using any activating agent. Electrocatalytic study indicates that amazingly the activity of the iodine-treated sample is found to be much better than that of untreated sample. This remarkable upsurge in activity is mainly attributed to the high increase in conductivity and surface area of the iodine-treated sample. The ORR activity is discussed in terms of heteroatom content, surface area, porous structure, and conductivity of the carbon [4-6]. This convenient innovative approach can open up a window for the designing of highly efficient future fuel cell electrocatalysts.

# A Recyclable Reaction Medium: Applications to Oxidative and Reductive Organic Electrochemical Transformations

R. Daniel Little,<sup>a</sup> Seung Joon Yoo,<sup>a</sup> Sebastian Herold,<sup>b</sup> Long-Ji Li,<sup>c</sup> Cheng-Chu Zeng,<sup>c</sup>

<sup>a</sup> *Department of Chemistry & Biochemistry, University of California Santa Barbara*

<sup>b</sup> *Graduate School Materials Science in Mainz, Germany*

<sup>c</sup> *Beijing University of Technology*

*little@chem.ucsb.edu*

The need for a supporting electrolyte in preparative scale electrosynthetic processes is clear. Several years ago, Yoo and Little initiated an effort one of whose goals was to devise a conveniently prepared and reusable reaction medium that avoided the use of a traditional supporting electrolyte.

Yoo's successes and the nature of the reaction medium, a so-called composite dispersion, will be described.[1] Its applicability to a variety of different oxidative transformations and its extension to reductive processes will be presented. An electrohydrocyclization that was previously used in the synthesis of a sesquiterpene called sterpurene will be revisited within the context of the new reaction medium.[2] The challenges associated with a) extending the scope of the chemistry to more challenging reductive processes, b) the problems encountered, c) the insights obtained, and d) the "solution(s)" devised will be highlighted.

## Abstract

Graphene, a one-atom-thick, two-dimensional (2D)  $sp^2$  carbon structure, has attracted considerable interest as a next-generation electrode material. This can be attributed to a number of interesting properties of graphene, such as its good mechanical/chemical stability, high electrical/thermal conductivity, and a large surface area (over  $2630\text{ m}^2\text{g}^{-1}$ ) due to its high surface-to-volume ratio. The combination of these unique physical and chemical properties means that graphene has significant potential to act as either an electrochemically active material in itself or as a conductive carbon template suitable for use in energy storage devices such as supercapacitors and Li-ion batteries.<sup>1-3</sup> At the same time, metal oxide/graphene nanocomposites are also of considerable interest for electrochemical energy storage applications owing to their outstanding properties. These excellent properties of metal oxide/graphene nanocomposites are generated from synergistic combination of graphene with metal oxide on the nanometer scale.<sup>1-3</sup> In this study, we report on the synthesis and electrochemical characterization of graphene and metal oxide/graphene nanocomposites for energy storage applications.

E-mail: [christine.kranz@uni-ulm.de](mailto:christine.kranz@uni-ulm.de)

Molecular transport on a cellular level plays a crucial role within the human body, and entails shuttling specific molecules and ions through the cell membrane via specific protein pores or ion channels. As natural membranes are exceedingly complex and exist in a variety of composition, artificial membranes such as lipid bilayers and supported lipid bilayers are frequently used as surrogates to investigate fundamental transport processes. To study such transport phenomena, electrochemical methods, in particular scanning electrochemical microscopy (SECM) [1,2] using nano-sized electrodes or ion selective micropipettes are highly attractive.

Here, we present electrochemical studies using cyclic voltammetry and combined atomic force – scanning electrochemical microscopy (AFM-SECM) to characterize transport through pore-forming proteins titrated into solid-supported lipid layers. As a model system, the trypsin-activated transport component C2IIa produced by *Clostridium botulinum* bacteria is investigated. The clostridium botulinum C2 toxin is a binary toxin using receptor-mediated endocytosis, and a C2IIa-mediated translocation of its C2I enzymatic component into the cytosol of mammalian cells, thereby developing the toxic effect within the cell after activation [3]. C2IIa forms heptameric pores, which are selective for cations and voltage dependent, and which spontaneously incorporate into lipid bilayers.

Gold-substrate-supported lipid bilayers (SLB) were formed via 1-octadecanethiol (ODT) and 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC). Bulk cyclic voltammetry experiments were performed to characterize the individual steps of the biomimetic layer formation, and the C2IIa pore incorporation. To investigate that the transmembrane transport is selectively induced by C2IIa pore incorporation, the antidote chloroquine was added to block the immobilized pores [4]. In addition, AFM-SECM was evaluated as a novel tool for monitoring the formation of pores by recording AFM-SECM approach curves at AFM tip-integrated conical Pt/C composite electrodes [5]. Experimental challenges and technological potential of characterizing the formation and transport properties of protein pores will be discussed in this contribution.

# **Light Activated Electrochemistry: A strategy for performing voltammetry on a monolithic surface where you want, when you want with micron scale spatial resolution**

Moinul Choudhury, Simone Ciampi, Stephen G. Parker, Ying Yang, Roya Tavallaie, Leila Zarei, Vinicius Goncales, J. Justin Gooding

*School of Chemistry and Australian Centre for NanoMedicine, The University of New South Wales, Sydney, 2052, Australia*

*E-mail: [justin.gooding@unsw.edu.au](mailto:justin.gooding@unsw.edu.au)*

Light and electrodes have a long history with spectroelectrochemistry, electrochemiluminescence and photovoltaics. Here we exploit light shined on an electrode to locally activate the electrode surface to allow Faradaic electrochemistry to occur on the illuminated spot only. To achieve this, first an oxide free silicon electrode is modified with a self-assembled monolayer of 1,8-nonadiyne which protects the surface against oxidation. Subsequently a redox species is attached to the surface, either a ferrocene derivative for n-type silicon or an anthraquinone derivative for p-type silicon. Provided the silicon is in the depletion at the potential at which the oxidation/reduction of the redox species occurs, then no electrochemistry is observed in the dark. Upon illumination distinct Faradaic electrochemistry is observed. We show this electrochemistry can be confined to 50  $\mu\text{m}$  with backside illumination and 30  $\mu\text{m}$  with frontside illumination. Subsequently, using SECM we show that the surface bound redox species can be used as a mediator to detect redox species in solution. We next show that we can detect DNA hybridization and form DNA electrode arrays (an example of reading electrochemical information from the electrode surface) and show that we can write conducting polymers to the surface. Finally we demonstrate an application for the capture and localized release of cells from the surface.

## **Alkaline polymer electrolyte fuel cells: materials and catalysis**

Lin Zhuang\*

*Department of Chemistry, Wuhan University, Wuhan 430072, China  
lzhuang@whu.edu.cn*

In this invited keynote lecture, I will talk about the recent research progress on alkaline polymer electrolyte fuel cells (APEFC), a promising new branch of the fuel cell family. The following topics will include:

- ✧ The state-of-the-art of alkaline polymer electrolytes
- ✧ Hydrogen oxidation reaction (HOR) catalysts in alkaline media
- ✧ Nonprecious metal catalysts for oxygen oxidation reaction (ORR) in alkaline media
- ✧ The performance and challenge of APEFC.

## Analysis by EIS of Cathodic Reactions on Carbon Steel in Aerated Solution at pH 13

B. Tribollet<sup>1,2</sup>, S. Chakri<sup>1,2</sup>, I. Frateur<sup>1,2</sup>, F. Kanoufi<sup>3</sup>, E. Sutter<sup>1,2</sup>, V. Vivier<sup>1,2</sup>

*bernard.tribollet@upmc.fr*

At pH 13, the carbon steel is passivated at the corrosion potential and the oxide layer is reduced at more cathodic potential. The transition potential between a carbon steel electrode coated by an oxide layer and a bare (*i.e.* oxide-free) electrode is difficult to determine by electrochemical measurements, but surface reflectivity measurements clearly show that transition.

In aerated solution, the oxygen reduction is a pure kinetic reaction at the corrosion potential but it is under mixed control at more cathodic potential, and finally the reaction is under pure mass transport control on the diffusion plateau and at very cathodic potential. For the lowest cathodic potentials, the water reduction occurs and must be added in parallel with the oxygen reduction.

From the corrosion potential ( $\sim -0.65$  V/SME) down to the cathodic potential limit ( $-1.70$  V/SME), the electrochemical impedance (EIS) data obtained with a C15 carbon steel electrode in aerated 0.1 M NaOH solution were analyzed considering for the cathodic reaction(s):

- oxygen reduction on the oxide-coated electrode with a pure kinetic control,
- oxygen reduction on the oxide-coated electrode with a mixed control,
- oxygen reduction on the bare electrode with a mixed control,
- oxygen reduction on the bare electrode with a pure mass transport limitation,
- oxygen reduction with a pure mass transport limitation and water reduction on the bare electrode.

The evolution with potential of the different kinetic parameters obtained from the fitting procedure is in agreement with the proposed models. In particular, the values of the oxide layer thickness deduced from EIS data are similar to those estimated from surface reflectivity measurements.

# Novel Electrochemical Prototype for the Treatment of Spent Caustic from Hydrocarbon Industry and its Industrial Scaling

A. Medel\*, G. Zuñiga, J. A. Ramírez, Yunny Meas\*

*Centro de Investigación y Desarrollo Tecnológico en Electroquímica, S.C., Parque Tecnológico, Querétaro-Sanfandila, P.O. Box 064-76703 Pedro Escobedo, QRO, México. Phone: +52-442-211-6000, Fax: +52-442-211-6001*

*\*email: yunnymeas@cideteq.mx; amedel@cideteq.mx*

*Oral presentation: Symposium 10:*

*Electrochemical Technology: New Challenges for a More Competitive Economy*

The spent caustic generated by the hydrocarbon industry is an extremely toxic aqueous residue, with a concentration of phenolic compounds in the range 10,000-30,600 mg L<sup>-1</sup>. The high and irreparable damage to the environment, as well as human health risk, posed by the inadequate disposal and treatment of spent caustic requires the development of new and efficient processes in order to achieve its treatment and destruction up to CO<sub>2</sub> and water. In this symposium we present the development of a new electrochemical process based on the use of Boron Doped Diamond (BDD), MO<sub>x</sub>/Ti and Graphite. The study conducted is the result of a grand research project, divided into separate phases, beginning with the development of a methodology for BDD activation [1], as well as of exhaustive characterization and micro-electrolysis tests of water produced [2] and spent caustic [3], ending with the scaling and fabrication of a prototype with a potential for industrial use. To carry out this project and to drive the use of electrochemical technology through the use of the BDD, each research phase, as well as the optimization of the operation variables, was carried out by means of the construction and implementation of a specialized infrastructure. At a laboratory level, the optimization of the operation variables was based on the analysis of the hydroxyl radical ( $\bullet\text{OH}_a$ ). The grade of mineralization of the phenolic compounds and its toxicity was evaluated by means of total organic carbon (TOC) analysis and use of the luminescent bacteria *Vibrio fischeri* (photobacterium phosphoreum). When comparing the efficiency of treatment with BDD with regard to the use of MO<sub>x</sub>/Ti and Graphite, in terms of the chemical oxygen demand (COD), percentages of 90 and 60-80% were obtained. The results obtained are discussed based on the production of different electro-generated oxidizing agents in addition to  $\bullet\text{OH}_a$  and simple electron transfer processes. Strategically, the evaluation of the prototype developed was carried out using MO<sub>x</sub>/Ti electrodes in order to evaluate and validate the potential use of the process of electrochemical conversion of phenolic compounds present in spent caustics, before proceeding to their total destruction or electrochemical incineration using BDD electrodes. Additionally, through the development of this new electrochemical process [3], 10% of the hydrocarbons present could be recovered, in this way causing a positive economic impact in the petrochemical industry by reducing the elevated costs of disposing of spent caustic and/or by salvaging the raw materials. The magnitude of this project and its importance is not only reflected in the reduction of costs for the petrochemical sector but also, and of even greater importance, in the elimination of the potential environmental impact and human health risk that a spill of spent caustic represents.

# Novel Hybrid Materials Prepared from Polymer Brushes and Graphene

Kim Daasbjerg

Carbon Dioxide Activation Center (CADIAC), Interdisciplinary Nanoscience Center, and Department of Chemistry, Aarhus University  
Gustav Wieds Vej 14, 8000 Aarhus, Denmark  
kdaa@chem.au.dk

Our recent research efforts are concerned with the development of surface modification tools as applied to the study of polymer brushes, coatings, hybrid materials, and composites. Functionalization of various substrates is of interest in many research fields, including life science<sup>1</sup> and molecular electronics.<sup>2</sup> One of the technologies employed in our group is construction of covalently attached polymer brushes from electrochemically modified surfaces,<sup>3,4</sup> where the covalent linkage is pertinent to ensure a high durability of the interfaces. In particular, the possibility of introducing new technologies for coating purposes seems appealing.<sup>5</sup> Polymeric systems containing a reactive side chain such as poly(glycidyl methacrylate) (PGMA) brushes are highly promising, in that the epoxide group readily reacts with various nucleophiles to provide further functionalization. Recently, we demonstrated that PGMA brushes grown by surface-initiated atom transfer radical polymerization (ATRP) on glassy carbon could be used as a versatile chemical platform for the construction of dual-functionalized organic films (Scheme 1).<sup>6</sup>

**Scheme 1.** Poly(glycidyl methacrylate) Brushes Grown by ATRP from Electrochemically Modified Glassy Carbon Followed by Chemical Modifications to Create Dual-Functional and Electrochemically Addressable Polymer Brushes.<sup>6</sup>

In this context, we have also considered graphene as substrate material due to its exceptional strength and barrier abilities. This may be exploited to improve the properties of a polymer matrix, once the graphene through functionalization is made compatible with the matrix.<sup>7</sup> In fact, a controlled electrochemical carboxylation of graphene provides a straightforward way of forming new hybrid materials via carboxylate groups as linker units.<sup>8</sup>

# Advances in the Growth of Metals and Alloys Assisted by a Monolayer Amount of UPD Atoms

Nikolay Dimitrov

*Department of Chemistry*

*Binghamton University - SUNY, P.O. Box 6000, Binghamton, NY 13902-6000,*

*e-mail: dimitrov@binghamton.edu*

In the realm of ever increasing importance of nanotechnology, the deposition of ultrathin metal / alloy layers with perfect structure and unique functionality becomes an objective of paramount importance. Aiming at epitaxial metal deposition in solution a pioneering work in the beginning of this century of Sieradzki et al. introduced the defect mediated growth (DMG) [1] and surfactant mediated growth (SMG) [2] as first electrochemical approaches where underpotentially deposited (UPD) atoms were intended to mediate the growth of ultra thin and continuous metal layers. In both methods, potentially controlled protocols ensure efficient manipulation of the UPD mediated deposition kinetics. Later on work of Dimitrov's and Stickney's groups described in details the development of new method for epitaxial thin film growth referred to as surface limited redox replacement (SLRR). This method inspired by a pioneering work of Brankovic et al. realizes as a "building block" reaction the replacement of a pre-deposited sacrificial (in most cases UPD) metal by the growing metal. Successive recurrence of this step results in coformal metal deposition. Work constituting advances in the field was done in understanding and first principle modelling of the SLRR protocol. Most recently, the SLRR development was extended to the application of all-electroless approaches for carrying out the SLRR (ESLRR). Finally, an effort is ongoing to utilize the power of UPD mediated functionalization for the design and development of a new generation of potent catalysts with applications in energy storage and generation. While the work of different research groups has been spread over the growth of a variety of metals including Cu, Ag, Pd, Pt and Ru as well as some of their alloys by DMG, SMG, SLRR, and ESLRR, no systematic comparison of growth regimes, resulting structure, morphology, thickness control, efficiency, limitations and/ or drawbacks has ever been presented for those approaches.

In the beginning of this presentation an overview of DMG, SMG, SLRR and ESLRR will first be presented. A comparison of the proposed mechanism will be made with emphasis on the ability of those methods to produce epitaxial, flat and uniform deposits. In the course of this comparison illustrations will be provided with results, illustrating the advantages and limitations of these deposition approaches in the growth of Ag and Cu thin films on Au (111) substrates. To support the discussion, on the approaches employed, results of electrochemical, in-situ scanning tunneling microscopy (STM), X-ray Photoelectron Spectroscopy characterization experiments will be presented and compared.

In the second part, the applicability of SLRR and ESLRR in the growth of Pt and Pt-based alloys on Au (111) substrate will be discussed. Experimentally demonstrated will be the SLRR growth of Pt layers with controllable thickness taking place in "shuttling" chamber, flow cell, and "one-pot" configuration. Open circuit potentiometry during the replacement reaction will be shown as a way to control the completion of each deposition event. Anodic stripping of the entire multilayer will be used for determining the overall film thickness. Cyclic Voltammetry and STM will be employed to characterize the growth of Pt and Pt-alloy layers with up to 10 nm thickness. High-resolution STM results and modelling concepts underlying the foundation of the proposed approaches will shed light on the mechanistic aspects associated with the nature of growth by redox exchange at a monolayer level.

In the third component of this presentation an overview of recent work on the design of potent catalysts with application in energy production and storage will be presented. This will include the use of SLRR approach for coating nanoparticles and continuous nanoporous metal layers with ultra thin films of metal / alloy with specific functionality. Successful outcome of this coating renders the final product catalytically active. In this part, a brief description will be provided also on the direct use of SLRR based protocols for the smart design of bimetallic alloy and/or core shell clusters with application in the most commonly used reactions in the field of fuel-cell catalysis. The discussion on the synthetic component of all relevant activities will be concluded with demonstration of results of testing of accordingly developed catalysts. Finally, a glimpse into the future of this rapidly developing field will be also provided.

# Electrode Structural Effects on Solid Oxide Electrolyser Performance

N. Farandos, A. Hankin, G.H. Kelsall, L. Kleiminger  
 Department of Chemical Engineering, Imperial College London  
 South Kensington, London SW7 2AZ, UK  
 g.kelsall@imperial.ac.uk

Energy conversion efficiencies of solid oxide fuel cells (SOFCs) and electrolyser (SOEs) operating at  $> 600^\circ\text{C}$ , can be increased principally by increasing densities of triple phase boundaries (electrode | electrolyte | reactant gas in pores) where reactions such as  $\text{CO}_2$  and / or  $\text{H}_2\text{O}$  splitting occur:

SOFCs and SOEs with infiltrated-scaffold composite electrode structures have been shown to have greater densities of triple phase boundaries (TPBs), and enhanced control of particle size and porosity compared with structures derived from powder mixing [1]. However, methods that fabricate reproducible, tailored scaffolds with micrometre length scales have yet to be reported. Hence, we are developing 3D printing ('additive manufacturing'), using a Ceradrop X-Series inkjet printer with multi-nozzle print heads, to fabricate reproducible, structured metal oxide frameworks with ca.  $50\ \mu\text{m}$  lateral and  $< 1\ \mu\text{m}$  vertical resolutions, prior to sintering. Ultimately, this should enable fabrication of percolated (porous) cathode | (non-porous) electrolyte | (porous) anode structures more reproducibly and with greater definition than hitherto, to achieve increased energy conversion performances. The reproducible geometries will also enable more facile comparison of experimental data and model predictions [2].

One prerequisite is the development of stable dispersions ('inks') of sub-micrometre sized metal oxide particles (i.e.  $(\text{ZrO}_2)_{0.92}(\text{Y}_2\text{O}_3)_{0.08}$ , NiO,  $\text{La}_{1-x}\text{Sr}_x\text{MnO}_{3-\delta}$ ) in liquid phases with suitable solids fractions and physical properties, to enable printing of the functional layers of SOFCs/SOEs (Fig.1). However, geometries of electrode | electrolyte structures are subject to limitations imposed by the requirement to minimise the spatial distributions of potential and current densities. Hence, results will also be presented for predictions (Fig.2) of those parameters, modelled using finite element software, together with preliminary current density-potential difference data for a printed SOE.

Firstly, yttria-stabilized zirconia (YSZ) particles were deposited onto a planar YSZ-NiO substrate, as precursors to a thin (ca.  $10\text{-}30\ \mu\text{m}$ ) gas-tight electrolyte (Fig. 1), formed by heating the green structure to ca.  $600^\circ\text{C}$  to burn out organics used to stabilise ink particles against aggregation, then sintered at ca.  $1450^\circ\text{C}$ .

Fig. 1. YSZ particles printed onto YSZ-NiO substrate, then sintered to a ca.  $30\ \mu\text{m}$  gas-tight electrolyte

Fig. 2. Finite element predictions of potential distribution on 'infiltrated' Ni-YSZ scaffold electrode.

t-mashio@mail.nissan.co.jp

Polymer electrolyte membrane fuel cells (PEMFCs) are promising power sources for the automotive use. Cost reduction is the primary concern associated with commercialization of fuel cell electric vehicles (FCEVs). The reduction of Pt usage in catalyst layers (CLs) without sacrificing power density is indispensable for the cost reduction of PEMFCs. CL is random porous media, which generally consists of Pt deposited on carbon supports and proton conducting ionomer. The proton conducting ionomer is essential for proton transport, while excess amount of ionomer hinders both reactant gas transport and electrochemical reaction.[1-3] The structure optimization of ionomer is highly desired in order to reduce Pt usage in CLs. Despite the importance of optimizing ionomer structure, morphology of ionomer in CLs and the mechanism of how ionomer structure is formed during the fabrication processes are still controversial due to the difficulty of experimental analysis.

We have been analyzing the structure and properties of CLs from characterization and modeling aspects, in order to understand the microstructure formation during fabrication process and its influence on performance.[4] In the presentation, challenges and update of the CL analysis in Nissan will be introduced with experimental data and simulation results.

There remain some issues for lithium ion batteries (LIBs) to grow in the application to advanced vehicles. Durability is the most important one among them because that gives a great impact on safety and cost.

Most of LIBs are composed of composite electrodes as positive and negative electrodes. Uniform reactions through the composite electrode lead LIB to the highest performance. Even very uniform distribution of their composition including porosity causes the reaction distribution along the thickness of the composite electrode due to electric and ionic conductivities.

Some researchers have published simulation results of reaction distribution in composite electrodes, but reports of distribution measurements, especially on operand *in situ* measurements are very limited. Synchrotron radiation X-ray is a very powerful tool to examine a reaction distribution in composite electrodes. The authors have devised some methods to measure operand *in situ* reaction distributions. The figure shows reaction distribution on the surface of composite electrodes of  $\text{LiFePO}_4$  at different AB contents.

To meet growing demands for electric automotive and regenerative energy storage applications, researchers all over the world have sought to increase the energy density of electrochemical capacitors. Hybridizing battery and capacitor electrodes can overcome the energy density limitation of the conventional electrochemical capacitors because they employ both the system of a battery-like (redox) and a capacitor-like (double-layer) electrode, producing a larger working voltage and capacitance. However, to balance such asymmetric systems, the rates for the redox portion must be substantially increased to the levels of double-layer process, which presents a significant challenge.

An in situ material processing technology called “ultracentrifuging (UC) treatment” has been used to prepare a novel ultrafast  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  (LTO) nanocrystal electrode for capacitive energy storage. In the present paper, the author will describe an extremely high performance supercapacitor that utilizes highly optimized “nano-nano-LTO/carbon composites” prepared via the UC treatment. The UC-treated LTO nanocrystals are grown as either nanosheets or nanoparticles, and both have hyperlinks to two types of nanocarbons: carbon nanofibers and supergrowth (single-walled) carbon nanotubes. The spinel structured LTO has been prepared with two types of hyperdispersed carbons. The UC treatment at 75000G stoichiometrically accelerates the in situ sol-gel reaction, hydrolysis followed by polycondensation, and further forms, anchors, and grafts the nanoscale LTO precursors onto the carbon matrices. The mechano-chemical sol-gel reaction is followed by a short heat-treatment process in vacuo. This immediate treatment with heat is very important for achieving optimal crystallization, inhibiting oxidative decomposition of carbon matrices, and suppressing agglomeration.

Such nanocrystal composites can store and deliver energy at the highest rate attained to this date. The charge-discharge profiles indicate a very high-sustained capacity of 80 mAh/g at an extremely high rate of 1200 C. Using this ultrafast material, we assembled a hybrid device called a “Nanohybrid capacitor” that consists of a Faradaic Li- intercalating LTO electrode and a non-Faradaic AC electrode employing an ion adsorption-desorption process. The “nanohybrid capacitor” cell has demonstrated remarkable energy, power, and cycleability performance as an electrochemical capacitor electrode. It also exhibits the same ion adsorption-desorption process rates as those of standard activated carbon electrodes in electrochemical capacitors.

The new-generation “Nanohybrid capacitor” technology produced more than triple the energy density of a conventional electrochemical capacitor. Moreover, the synthetic simplicity of the high-performance nanostructures makes it possible to scale them up for large-volume material production and further applications in many other electrochemical energy storage devices.

# **Development of Drug Delivery Devices Based on Nongassing Electroosmotic Pump**

Woonsup Shin

*Department of Chemistry and Interdisciplinary Program of Integrated Biotechnology, Sogang University, Seoul  
121-742, Republic of Korea  
[shinws@sogang.ac.kr](mailto:shinws@sogang.ac.kr)*

Electrochemistry is known to be a key transducing technology between chemical energy and electrical energy. Electroosmosis is a phenomenon which the fluid moves upon applying electric field through capillary or porous ceramic membrane. This is a rare example where electrochemistry is utilized for a mechanical transducer. Electroosmotic pumps are the simplest among all the pumps, consisting of two electrodes separated by a porous membrane, but its practical use has been hindered by the use of platinum electrode. On platinum the pumped solution keeps being electrolyzed to produce  $O_2$  from anode and  $H_2$  from the cathode and the bubbles are easily trapped in the membrane to make the flow irregular. Even the co-production of  $O_2$  and  $H_2$  makes the system unsafe in the closed loop. The use of electrochemical reaction such as  $Ag/Ag_2O$  could substitute the reactions on the platinum electrode to operate the pump non-gassing with higher efficiency. It also enabled the pump battery-operable. The pump is now currently used to develop drug pumps such as insulin patch pump and implantable morphine pump.

# Corrosion Electrochemistry and Surface Film Properties of Alloy 690 in High Temperature Pressurized Water

En-Hou Han, Jianqiu Wang, Xinqiang Wu, Zhiming Zhang  
*Institute of Metal Research, Chinese Academy of Sciences*  
62 Wencui Road, Shenyang 110016, China  
ehhan@imr.ac.cn

The steam generator tubing of pressurized water reactors (PWRs) are fabricated by nickel-based alloy 690 during last 20 years since their superior resistance to general corrosion and stress corrosion cracking in the primary side of the nuclear reactor. It was generally recognized that the nucleation and propagation of localized corrosion was strongly related to the properties of the oxide film formed on the metal surface. A considerable number of investigations have been devoted to the identification of the oxide film. However, the oxide film formed in high temperature water is difficult to be characterized. The objective of this work was to investigate the electrochemical behavior and the oxide film properties of alloy 690 in high temperature pressurized water, to understand the corrosion mechanisms, to improve the corrosion properties of alloy 690 and to insure the lifetime of steam generator.

The effects of dissolved oxygen (DO) and hydrogen (DH), pH of solution, surface finishing of material, and even Zn injection into the solution on the electrochemical behavior and the oxide film properties of alloy 690 in high temperature pressurized water by means of in-situ potentiodynamic polarization measurements, electrochemical impedance spectra (EIS), Mott–Schottky (MS) plots, ex-situ X-ray photoelectron spectroscopy (XPS), scanning electron microscopy (SEM), transmission electron microscopy (TEM) and Grazing incidence X-ray diffraction (GIXRD) in Synchrotron Radiation Facility (SSRF) analysis. The related growth mechanisms of the oxide films were also discussed.

The alloy 690TT samples were exposed in pure and the primary water of PWRs at 325°C and 15 MPa. The change in water chemistry from pure to primary water was found to vary the film structure from duplex to triple layer, and lead to change in the morphology of NiO on the surface. The increased pH and solution conductivity of primary water also accelerate the dissolution of Cr species and enhance the electrochemical corrosion. The Ni-rich and Cr depleted inner layer formed under both water chemistries is porous and not protective. Under higher DO, the oxide film mainly consisted of outer spinel particles and porous NiO base layer. A thin Cr-rich film gradually develops with decreasing DO. Fe and Ni levels in the film decrease while Cr level increases concomitantly. The film preformed under low DO becomes much thicker when immersed under high DO, with gradual development of spinel particles and NiO base layer. The surface roughness and micro-hardness decreased gradually from the ground to mechanical polished and electro polished surfaces. The grains in the near-surface layers of the ground and mechanical polished surfaces had been refined and the residual strains were also very high with parallel dislocation lines. The thickness of the superficial cold-worked layers decreased gradually from the ground surfaces to polished surfaces. The oxide morphologies and oxidation rate depended greatly on the surface states of samples. Cold-working by grinding treatments could benefit the outward diffusion of metallic atoms and the nucleation of surface oxides and then accelerate the growth of surface oxide films. With Zn injection in the solution,  $\text{ZnCr}_2\text{O}_4$  and  $\text{ZnFe}_2\text{O}_4$  were formed in the inner and outer layers of the oxide films on Alloy 690, respectively, through exchange reactions between  $\text{Zn}^{2+}$  and  $\text{Fe}^{2+}/\text{Ni}^{2+}$ .

# Advanced Cathodes and Metallic Anodes for Next-Generation Rechargeable Batteries

Yu-Guo Guo\*

*Institute of Chemistry, Chinese Academy of Sciences (CAS)*

*Beijing 100190, P. R. China*

*e-mail: ygguo@iccas.ac.cn*

Next-generation rechargeable batteries with high energy densities are the most important cutting-edge science and technology [1-3]. Among various candidates, rechargeable lithium batteries using metallic Li or Na as the anodes, and chalcogen elements (O, S, Se, etc.) as the cathodes are most promising [1-3]. Here, we report our recent progress in this field covering Li-S, Li-Se, room-temperature Na-S, Na-Se, as well as Mg(-ion) batteries [4-9]. We show that rational design of these cathode materials could play an important role in improving the performance of these rechargeable metal batteries. We report the electrochemistry of chalcogen elements (S, Se, Te) with different allotropies (cyclic and chain-like molecules). Especially, we report our recent progress on the electrochemical deposition/dissolution processes, and the evolution of interfacial chemical composition and structure of the metallic Li anodes, as well as Li-S and Li-Se pouch cells (2~10 Ah).

# Surface-Enhanced Infrared Absorption Spectroscopy (SEIRAS): Shedding Light on The Electrochemical Interface

Masatoshi Osawa

*Catalysis Research Center, Hokkaido University*

*N21W10, Kita-ku, Sapporo 001-0021, Japan*

*osawam@cat.hokudai.ac.jp*

Surface-enhanced infrared absorption (SEIRA) is an effect in which infrared absorption of molecular species on metal surfaces is greatly enhanced.<sup>1</sup> This effect is similar to surface-enhanced Raman scattering (SERS) in nature, but there are some differences between them. The most important is that SEIRA is applicable not only to coinage metals but also to transition metals including Pt and Pt group metals. From this point of view, SEIRAS has wider applications than SERS in principle. Unfortunately, however, the enhancing mechanism of IR absorption has not been fully understood yet. In this talk, a new theoretical model for SEIRAS, an extended version of an old one,<sup>2</sup> will be presented first and, on the basis of the theoretical consideration, it will be discussed how SEIRAS experiments should be designed and what can we obtained from SEIRA spectra.

# The aqueous electrochemical capacitor: a high energy alternative solution to organic electrolyte-based systems

Patryk Przygocki, Qamar Abbas, Paula Ratajczak, François Béguin

Poznan University of Technology, Institute of Chemistry and Technical Electrochemistry, Berdychowo 4, 60-965 Poznan, Poland

[francois.beguin@put.poznan.pl](mailto:francois.beguin@put.poznan.pl)

Activated carbon (AC) based electrochemical capacitors in organic (TEABF<sub>4</sub>/acetonitrile) and aqueous (KOH and H<sub>2</sub>SO<sub>4</sub>) electrolytes have been extensively investigated during the last decade. However, due to the environmentally unfriendly character of the former and low operating cell potential of the later, alternative electrolytes are desirable. Recently, capacitors based on salt aqueous electrolyte e.g., 1 mol L<sup>-1</sup> Li<sub>2</sub>SO<sub>4</sub> (pH = 6.5), capable of operating up to 1.5 - 2 V have been reported [1-3]. Such high cell potential is realized owing to the high over-potential for di-hydrogen evolution at the negative AC electrode [2]. Besides, high capacitance (C) was demonstrated by realizing AC/AC capacitors in aqueous solution of potassium iodide, owing to hybridization between the I<sup>-</sup>/I<sub>2</sub> redox positive electrode and the typical EDL negative one. However, in this electrolyte, the cell potential (U) is limited to 1.2 V [4]. This presentation will show strategies based on aqueous electrolyte optimization for simultaneously enhancing cell potential, capacitance and operating temperature range.

An aqueous mixture of 2 mol L<sup>-1</sup> manganese sulfate (MnSO<sub>4</sub>) and 0.5 mol L<sup>-1</sup> potassium iodide (KI) with pH = 3 has been used in order to get synergy between the I<sup>-</sup>/I<sub>2</sub> redox couple at the positive electrode and high cell potential allowed by MnSO<sub>4</sub>. Galvanostatic two-electrode cell experiments up to potential of 1.5 V demonstrate that the addition of KI to MnSO<sub>4</sub> results in enhanced cell capacitance of 93 F g<sup>-1</sup> compared to 41 F g<sup>-1</sup> for MnSO<sub>4</sub> (Fig. 1a). Interestingly, the presence of iodide improves the cycle life under potentiostatic floating at 1.5 V for 120 hours, where the capacitor exhibits constant capacitance of ~55 F g<sup>-1</sup> and low resistance of 2 Ω (Fig. 1b). Experiments in two-electrode cells with a reference electrode show that, at pH = 3, the I<sup>-</sup>/I<sub>2</sub> redox couple is highly active at the positive AC electrode with a small potential window, while the negative AC electrode mainly exhibits an EDL behavior, determining the overall capacitive performance of the system. The AC/AC capacitor based on the MnSO<sub>4</sub> + KI electrolyte displays comparable energy density at 0.2 A g<sup>-1</sup> current load to the one using the same carbon in TEABF<sub>4</sub>/acetonitrile.

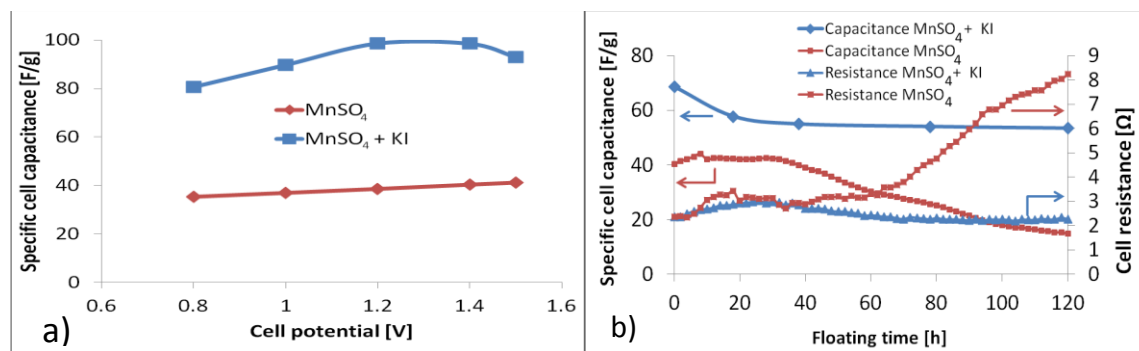

Fig. 1 AC/AC capacitors in 2 mol L<sup>-1</sup> MnSO<sub>4</sub> and 2 mol L<sup>-1</sup> MnSO<sub>4</sub> + 0.5 mol L<sup>-1</sup> KI: (a) Specific cell capacitance vs. cell potential; (b) specific cell capacitance and cell resistance during floating at 1.5 V.

MnSO<sub>4</sub> and MnSO<sub>4</sub> + KI aqueous electrolytes containing an antifreezing additive have been further designed and implemented in the AC/AC capacitor, demonstrating possible operation down to -30°C. The mechanisms playing in the system when temperature is reduced will be discussed.

# Development of Ambient Pressure XPS and its Applications to Electrochemistry

Bongjin Simon Mun

*Gwangju Institute of Science and Technology*

*123 Cheomdangwariro, Gwangju, Korea*

*bsmun@gist.ac.kr*

X-ray photoelectron spectroscopy (XPS) is one of the major tools in the fields of surface chemistry due to its excellent capabilities in studying surface chemical and electronic properties. However, due to the short inelastic attenuation lengths of photoelectrons, as well as the requirement of high vacuum in the electron spectrometer, only the model studies or ex-situ systems have been carried out, and thus creating so-called “pressure-gap”. In an effort to bridge this pressure-gap, the ambient pressure x-ray photoelectron spectroscopy (AP-XPS) has been continuously developed and now puts a new road map in the world of surface science with use of synchrotron radiation facility. [1]

In this presentation, the basic principles and the latest instrumental developments of AP-XPS will be presented. Also, the applications of AP-XPS to several practical systems will be given, including electrochemical system. Now, with the use of high-energy photon source, it becomes possible to run *in-situ* analysis of liquid/solid interface under operating condition.

# Graphene and Carbon Nanotubes for Bioelectrochemical applications

Michael Holzinger

University of Grenoble-Alpes – CNRS  
Département de Chimie Moléculaire, UMR 5250  
570 rue de la Chimie, BP 53  
38041 Grenoble, France  
michael.holzinger@ujf-grenoble.fr

Due to the increasing need to monitor health and environment in real time and to energize small electronic devices, new materials are under extensive investigations. Between others, carbon nanotubes (CNTs) and graphene are promising alternatives as building blocks in bioelectrochemical devices due to their unique electrical, mechanical properties, biocompatibility and high specific surface. In the past years, we focused the development of biosensors and biofuel cells based on such carbon nanostructures<sup>[1-3]</sup>. Our efforts in this domain aim the construction of nano-architecture at molecular scale associating different nano-objects via organic or organo-metallic connectors to immobilize redox enzymes<sup>[4]</sup>. Furthermore, our efforts focus redox enzyme wiring on nanotubes and graphene to enable direct electron transfer (DET)<sup>[5, 6]</sup>.

Particular interesting results were obtained by electropolymerization of pyrrole- or pyrene derivatives onto the CNT sidewalls to obtain highly functional nanostructured carbon receptors<sup>[7]</sup>. Such CNT modified electrodes offer a high specific surface with an excellent accessibility for the anchoring of proteins via affinity interactions<sup>[1]</sup>.

The possibility to generate electrical power *via* living organisms directed biofuel cell research towards glucose biofuel cells (GBFC) since the two required compounds (glucose and oxygen) are present in both, vegetal and body fluids. In this vein, the first implantation of a biofuel cell in the rat abdomen have paved the way for future applications of biofuel cells for continuous supply of implanted electronic devices such as pacemakers, insulin pumps, etc<sup>[8]</sup>. However, in spite of this promising evolution, there are still some issues to be resolved before enzymatic biofuel cells become competitive in practical applications. Two critical obstacles are short lifetime and poor power density, where both are related to enzyme stability, electron transfer rate, and enzyme loading. Our proposed design of bioelectrodes for enzymatic biofuel cells is based on a highly porous 3D nanostructured scaffold that allows high enzyme loading in a protective environment while allowing optimal flow of the “fuel” and oxygen containing solution<sup>[4]</sup>. Furthermore, this biofuel cell setup could successfully be implanted inside a rat and delivered sufficient power out of the rat’s extra cellular body liquids to light a LED and a digital thermometer<sup>[9]</sup>. However, even when some milestones could be overcome, some critical issues are still to resolve like long term stability and power output. In this context, some alternative approaches to optimize the electron transfer are presented.

## Abstract:

In this talk, we will present electrodeposition of highly oriented [111] Cu grains with densely packed nanotwins by DC and AC with a high stirring rate. Nearly 100% of the surface grains are [111] oriented. With the [111] oriented and nanotwinned Cu (nt-Cu), we can control the growth of Cu<sub>6</sub>Sn<sub>5</sub> intermetallics in the microbumps of 3D IC packaging. Therefore, a uniform microstructure in a large number of microbumps of controlled orientation can be obtained. Electron backscatter diffraction (EBSD) was employed to analyze the statistical distributions of surface grain orientations and the grain boundaries of the Cu and the Cu<sub>6</sub>Sn<sub>5</sub>. The results indicate that 96% of the columnar Cu grains have less than 10 degrees of misalignment with respect to

the [111] direction. In addition, EBSD orientation image maps for the  $\text{Cu}_6\text{Sn}_5$  compounds show a preferred orientation near the (0001) plane of the  $\text{Cu}_6\text{Sn}_5$ . The oriented nt-Cu can eliminate the Kirkendall voids during the solid-state aging in Cu-Sn reactions. In addition, with high diffusivity of Cu atoms on the (111) surfaces, Cu-to-Cu direct bonding can be achieved below 200°C at a compressive stress of 114 psi held for 30 min at  $10^{-3}$  torr, or at 150°C at for 60 min. The details will be presented in the conference.

## Abstract

Catalysts play a critical role in solar fuels and fuel cells. Not only there are only a few materials that function well enough, be it measured by the power/energy output, oxygen reduction reaction (ORR) activity, hydrocarbon fuels-production rate, selectivity and durability, *etc.*; but also, most of the champion catalysts reported so far is not earth-abundant or costly in process. In this talk, selective case studies on energy-conversion that utilizes low-cost nanostructures as their key components will be presented. Two different systems will be highlighted: (1) novel macrocyclic compounds to replace the precious metal-catalysts for fuel cells [1-3], and (2) photo-catalysts based on graphene oxides and their hybrids with MoS<sub>2</sub>, and Cu nanoparticles for CO<sub>2</sub> conversion [4-5]. It should be noted that exploration of the macrocyclic compounds as functional electro-catalysts was stimulated by biomimetic concept, *i.e.*, the principle learned from the nature. Whereas photo-catalytic conversion of CO<sub>2</sub> to hydrocarbons, the so-called artificial photosynthesis, makes possible simultaneous solar energy harvesting and CO<sub>2</sub> reduction, two birds with one stone for the energy and environmental issues. In addition to the usual microstructural characterizations, various synchrotron-radiation spectroscopic techniques, including XAS, XANES, and EXAFS, were also employed for studying the binding and electronic structures of these nano-structures, wherever appropriate. I will address how the spectroscopic techniques may help answering some key questions in their catalytic activity and conversion performance.

# Anodic Synthesis of Unnatural Peptide and Nucleic Acid Derivatives

Kazuhiro CHIBA, Takao SHOJI, Yohei Okada, Shokaku KIM

Department of Applied Biological Science  
Tokyo University of Agriculture and Technology  
3-5-8 Saiwai-cho, Fuchu, Tokyo 183-8509, Japan  
[chiba@cc.tuat.ac.jp](mailto:chiba@cc.tuat.ac.jp)

Although the anodic  $N$ - $\alpha$  C-H activation of  $N$ -carbonyl bonds is attractive for the synthesis of artificial proline analogues, there are significant limitations for further diversification in both the  $N$ -terminal and  $C$ -terminal directions. These limitations arise from the relatively high oxidation potential of  $N$ -carbonyl bonds, and the structural vulnerability associated with leaving groups at 5-position of proline. The electrochemical conversions cannot be directly applied to proline derivatives including the lower oxidation potential peptide side chain, protecting group and other functional units as compared with that of  $N$ -carbonyl bonds. Furthermore, replacement reactions in the  $N$ -terminal direction involving the deprotection of a proline  $N$ -protected with a 5-methoxy, trifluoroethoxy or acetoxy group generate unstable intermediates containing the hemiaminal ether bond; these intermediates decompose before they can engage in the subsequent reaction.

To address these problems, we explored viable electrochemical strategies for diversifying 5-substituted proline derivatives. Specifically, considering aspects of the oxidation potential and the lack of the stability, we sought to introduce a phenyl group as the leaving moiety: this intermediate should be stable as it avoids the *germinal* diheterolytic linkage. We then assumed that anodic oxidation of 5-trimethoxyphenyl proline would transiently form the radical cation, thus triggering C-C bond cleavage to deliver the  $N$ -acyl iminium cation and the phenyl radical. The resulting cation would couple with nucleophiles to provide 5-substituted proline derivatives. Furthermore, incorporation of electron-donating substituents into the phenyl group would lower the oxidation potential, thus enabling the use of various nucleophiles.

We therefore achieved anodic modification reactions of proline derivatives using the 2,4,6-trimethoxyphenyl moiety as a leaving group. 2,4,6-Trimethoxyphenyl at the 5-position of proline is stable during deprotection of the  $N$ - and  $C$ - termini and the subsequent modification reaction. Furthermore, the anodic substitution reaction proceeded *via* carbon-carbon bond cleavage at a lower oxidation potential due to the electron-donating property of the trimethoxy substituents.

In addition to the modification of prolyl peptides, we have developed a highly efficient synthetic method for azanucleosides, which allows the installation of various nucleophiles, including protected nucleobases, into prolinol derivatives directly and exclusively at the 5-position. The  $\text{LiClO}_4\text{-CH}_3\text{NO}_2$  system anodically converted prolinol derivatives to the corresponding iminium cation intermediates, which were stabilized and efficiently trapped by various nucleophiles. The applicability and limitations of this system are currently under investigation.

# **The Joint Center for Energy Storage Research (JCESR): A New Paradigm for Energy Storage Research**

George Crabtree

*Director, Joint Center for Energy Storage Research (JCESR)*

*University of Illinois at Chicago*

*845 W Taylor St, Chicago IL USA 60607*

*Argonne National Laboratory, 9700 S. Cass Ave, Argonne IL USA 60439*

*crabtree@anl.gov*

The Joint Center for Energy Storage Research (JCESR) pursues high performance, low cost beyond lithium ion electricity storage that will transform transportation and the electricity grid. JCESR will leave three legacies:

- a library of fundamental knowledge of the materials and phenomena of energy storage at the atomic and molecular level
- two prototypes, one for the grid and one for transportation, that, when scaled to manufacturing will be able to deliver five times the energy density at one-fifth the cost
- a new paradigm for battery R&D that combines discovery science, battery design, research prototyping and manufacturing collaboration in a single highly interactive organization, accelerates the pace of discovery and innovation and significantly shortens the time from discovery to commercialization.

An introduction to JCESR's vision, mission and legacies will be followed by research highlights from UIC illustrating its advances in fundamental science and the promising pathways to transformational battery designs and prototypes.

This work was supported as part of the Joint Center for Energy Storage Research, an Energy Innovation Hub funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences

# Molecular Electrochemistry: from Protons to Electrons, from Molecules to Molecular Nanoclusters

Flavio Maran

*Department of Chemistry, University of Padova  
via Marzolo 1, 35131 Padova, Italy  
flavio.maran@unipd.it*

Molecular electrochemistry is a discipline embracing topics such as electron-transfer (ET) induced transformation of molecules, associated chemical reactions, control of long-range and mediated ET reactions, and electrochemistry on electrodes and modified electrodes. The focus is always on molecular aspects. By following the steps of my mentor, the late Professor Elio Vianello, my initial research concerned organic electrochemistry and the kinetics and mechanism of proton-transfer reactions associated with the electrode processes. Analysis of self-protonation reactions allowed developing an original method for determining the  $pK_a$  of weak acids in *N,N*-dimethylformamide<sup>1</sup> and obtain crucial information on the very elusive  $\alpha$ -lactam intermediate.<sup>2</sup> My research gradually shifted toward the study of the mechanisms of dissociative ETs. For the first time, it was possible to: observe a quadratic activation – driving force relationship in the direct electroreduction of peroxides;<sup>3</sup> prove that peroxides undergo nonadiabatic dissociative ETs;<sup>4,5</sup> detect the continuous transition between concerted and stepwise heterogeneous ETs;<sup>6</sup> show that stepwise dissociative ETs may proceed very slowly through formation of loose radical anions;<sup>7</sup> establish a quantitative relationship between heterogeneous and homogeneous ET kinetics in a very wide intrinsic-barrier range.<sup>8</sup> Molecular electrochemistry proved to be very powerful also to study the distance effect on ET reactions.<sup>9</sup> My current interest is mostly on applying similar concepts and methodologies to the study of monolayer-protected gold nanoclusters. For gold cores of less than 1.5 nm, these clusters display truly molecular features, including very nice electrochemical behavior in organic solvents.<sup>10,11</sup> Some of their oxidation states can be used as efficient homogeneous ET mediators.<sup>10,12</sup> Very recently, we showed that heterogeneous ET provides a very efficient tool for assessing the structure of such protecting but not-so shielding monolayers.<sup>13</sup>

<sup>2</sup>*SUNCAT ctr for Interface Science and Catalysis, SLAC National Accelerator Laboratory, 2575 Sand Hill Road, MS 31, Menlo Park, CA 94070, USA*

We will demonstrate how electron and x-ray spectroscopy can be used to address fundamental questions regarding the reaction mechanism and active sites of the Oxygen Reduction Reaction (ORR), Oxygen Evolution Reaction (OER) and Hydrogen Evolution Reaction (HER). We have developed in-situ XPS capabilities using a membrane assembly where either the anode or cathode side is exposed to a differential pumped environments where direct measurements of the changes in the catalyst and various reaction intermediates can be probed during ORR on Pt, OER on IrO<sub>2</sub> and HER conditions for MoS<sub>2</sub>. We have also recently conducted high-energy resolution fluorescence detection (HERFD) studies of the Fe and Ni K-edges under OES conditions in the highly active Ni-Fi oxyhydroxides to determine the nature of the active sites. In particular we observe that Fe encounter an extremely strained local geometry when Ni undergoes a transformation from the 2+ to 3+ state.

# Understanding and Predicting the Photocatalytic Properties of Bismuth Vanadate from First Principles

Gyeong S. Hwang

*McKetta Department of Chemical Engineering, University of Texas at Austin*

*1 University Station C0400, Austin, Texas 78712, U.S.A.*

*gshwang@che.utexas.edu*

Renewable sources of energy are increasingly needed and solar production of hydrogen fuel from water offers significant potential to contribute to these needs. Bismuth vanadate ( $\text{BiVO}_4$ ) has received much interest as a promising visible-light-active photocatalyst for water splitting and pollutant decomposition. However, some fundamental aspects of its photocatalysis remain still unclear, including phase-dependent activity, doping effect, and surface reactivity. For instance, molecular mechanisms underlying the oxidative water splitting into molecular oxygen and proton are largely unexplored. In addition, charge localization and transport in  $\text{BiVO}_4$  and its effects on the photocatalytic performance need to be further explored. This talk will focus on discussing our recent findings from extensive first-principles calculations regarding the underlying mechanisms of the oxygen evolution reaction as well as the localization and transport of excess charge carriers. The improved understanding may offer important guidance for the rational design of photocatalytic materials.

# AN OVERVIEW OF THE BEHAVIOR OVERLITHIATED Li(Li,Mn,Co,Ni)O<sub>2</sub> LAYERED OXIDES IN LITHIUM-ION BATTERIES

**C. Delmas<sup>1</sup>, H. Koga<sup>1,2</sup>, L. Croguennec<sup>1</sup>, M. Ménétrier<sup>1</sup>, S. Belin<sup>3</sup>, C. Genevois<sup>4</sup> and F. Weill<sup>1</sup>**

The materials belonging to the (1-x)LiMO<sub>2</sub>.xLi<sub>2</sub>MnO<sub>3</sub> system (M = Ni, Co) exhibit the largest capacity among all other layered oxides. These materials are overlithiated layered oxides (Li<sub>1</sub>(Li<sub>y</sub>Mn<sub>1-y-u-t</sub>Co<sub>u</sub>Ni<sub>t</sub>O<sub>2</sub>) with a significant amount of lithium in the transition metal site. Depending on the starting composition, Mn ions can be tri- or tetravalent while Ni ions can be di- or trivalent. In the literature there is a strong debate about the existence of a solid solution or the presence of a composite structure. The structure of the obtained material depends on the composition and on the conditions of the thermal treatment. The cationic distribution is strongly related to the difference in charge and ionic radius.

A very general study of the synthesis and of the electrochemical characterization of the Li<sub>1.20</sub>Mn<sub>0.54</sub>Co<sub>0.13</sub>Ni<sub>0.13</sub>O<sub>2</sub> phase has been undertaken for several years in our lab. In order to have a better overview of its behavior a systematic study has been also carried out by chemical deintercalation. All the structural, electrochemical and physical characterizations show that these materials are very similar to those electrochemically obtained.

During the first charge, when all cations are oxidized to the tetravalent state, an overcharge of the cell leads to a structural modification that can be schematically described as a Li<sub>2</sub>O extraction occurs that cannot explain alone the oxidation process. Either oxidation of cations to a higher oxidation state or of oxygen is required. All experiments to detect cation oxidation state higher than four failed, so the oxidation of oxygen has been considered.

The contribution of oxygen to the redox activity in this material family is considered from several years. It was suggested in 2009 by Koyama *et al.* from first principle calculation in Li<sub>2</sub>MnO<sub>3</sub> [1], then by Kikkawa *et al.* in their Mossbauer study of the Li<sub>1.2</sub>Mn<sub>0.4</sub>Fe<sub>0.4</sub> phase [2] and more recently by Ito *et al.* from an XAS study on the Li<sub>1.20</sub>Mn<sub>0.56</sub>Co<sub>0.07</sub>Ni<sub>0.17</sub>O<sub>2</sub> phase [3]. In our lab we have clearly shown its occurrence in the case of the electrochemical (or chemical) cycling of the Li<sub>1.20</sub>Mn<sub>0.54</sub>Co<sub>0.13</sub>Ni<sub>0.13</sub>O<sub>2</sub> phase [4-5]. Sathiya *et al.* [6] also confirmed it in the case of the Li<sub>2</sub>Ru<sub>1-y</sub>Sn<sub>y</sub>O<sub>3</sub> system.

In order to clarify the mechanism which is involved during the overcharge a systematic study has been carried using chemical analysis, X-ray and neutron diffraction, in operando XAS, very high-resolution electron microscopy and Raman diffraction. During the high voltage plateau in the first cycle, there is a partial densification on the external part of the particles followed by an oxygen oxidation in the bulk of the lattice without oxygen migration. This redox process is completely reversible in discharge. The contribution of nickel and cobalt and oxygen reduction leads to the huge specific capacity of this material family.

A general overview of all reactions mechanisms will be presented.

## **Special Sites in Electrocatalysis**

Jan Rossmeisl

*Department of Chemistry, University of Copenhagen  
Universitetsparken 5, 2100, København Ø, Denmark.  
jan.rossmeisl@chem.ku.dk*

So far most electrocatalyst has been designed only based on reactivity of the surface. This single parameter is not sufficient to optimize the activity and selectivity. This means that activities and selectivity can only be optimized to a certain point. The activity as function of the surface reactivity is often represented in volcano curves. Electrocatalytic activity and selectivity is ultimately determined by the atomic and electronic structure of the catalyst surface. By controlling the atomic structure of the catalyst surface it is possible provide more parameters besides the reactivity to tune activity and selectivity beyond the normally limits. I will show some examples on atomic scale design of special electrocatalytic sites for oxygen evolution and oxygen reduction for better selectivity and activity.

# Operando Methods for the Characterization Energy Materials

Héctor D. Abruña

*Department of Chemistry and Chemical Biology*

*Director, Energy Materials Center at Cornell*

*Baker Laboratory, Cornell University*

*Ithaca, New York 14853-1301*

*hda1@cornell.edu*

This presentation will deal with the development of *operando* methods for the study and characterization of fuel cell and battery materials. The presentation will begin with a brief overview of the methods employed. Particular emphasis will be placed on the use of X-ray diffraction (XRD) and X-ray absorption spectroscopy (XAS), transmission electron microscopy (TEM) under active potential control, confocal Raman and differential electrochemical mass spectrometry (DEMS). The utility of these methods will be illustrated by selected examples including the use of Ge nanowires as lithium ion battery anodes, spectroscopic studies of Li/S batteries and the use of DEMS to characterize electrolyte systems for LIBs. The use of operando TEM will be illustrated by studies of fuel cell catalyst degradation and coalescence and lithiation/de-lithiation dynamics of  $\text{LiFePO}_4$  via energy-filtered TEM. The presentation will conclude with an assessment of future directions.

## Recent Progress of Porphyrin-Sensitized Solar Cells

Chen-Yu Yeh, Hsien-Hsin Chou, Chi-Lun Mai, Hsuan-Wei Lee, Sudhir Kamani, Guan-Jie Fang, Chia-Wei Hsu

Department of Chemistry, National Chung Hsing University, Taichung, Taiwan  
250 Kuo-Kuang Rd., Taichung 402, Taiwan  
cyyeh@dragon.nchu.edu.tw

Porphyrin dyes with a push-pull framework have been prepared and used in dye-sensitized solar cells (DSSC), their spectral, electrochemical and photovoltaic properties were investigated. The photovoltaic measurements show that **YD2-o-C8** achieves a record power conversion efficiency ~12% using Co(II)/Co(III) as the electrolyte. When **YD2-o-C8** is co-sensitized with an organic dye **Y123**, the device gives a power conversion efficiency of 12.3% under standard AM 1.5 sunlight, and 13.1% under AM 1.5 solar light of 500 W m<sup>-2</sup> intensity. In **YD2-o-C8**, The hydrophobic alkoxy chains at the *ortho*-positions of the *meso*-phenyls suppress molecular aggregation and successfully block the approach of the electrolyte to the surface of TiO<sub>2</sub> to reduce charge recombination, giving an improved *V<sub>oc</sub>* and the power conversion efficiency. Based on the structure of **YD2-o-C8**, a new porphyrin **GY50** with more red-shifted absorption has been synthesized. The device of **GY50** gives a power conversion efficiency of 12.75% under standard AM 1.5 sunlight. To improve the long term stability of the devices, pyridine-type anchors have been tested. It was demonstrated that 2-carboxypyridine is an efficient and stable anchoring group as **MH1** showed better cell performance and long-term stability than **YD2-o-C8** under light soaking conditions. We found that introduction of push and pull units to *meso*-positions is demonstrated to be achievable. Furthermore, bulky donors are compatible with cobalt-based electrolytes and yield high *V<sub>oc</sub>*, long alkyl chains at *meso*-phenyls successfully reduce dye aggregation and decrease charge recombination rate, and the benzoic acid acceptor is superior to the cyanoacrylic acid counterpart. These push-pull porphyrin dyes are promising candidates for highly efficient DSSC.

# Two-Dimensional Materials and Electrode Architectures for Capacitive and Pseudocapacitive Energy Storage

Y. Gogotsi

*A.J. Drexel Nanomaterials Institute and Department of Materials Science and Engineering, Drexel University, Philadelphia, PA, 19104, USA*

Electrical energy storage is a key challenge because our daily life depends on numerous electronic devices. Moreover, with miniaturization of electronics, penetration of wireless devices into our homes and clothes, wide use of sensor networks and widely anticipated “internet of things”, there is a major effort to develop miniature, but powerful storage devices. To satisfy the growing demand, new concepts must be formulated that will lead to a new generation of sustainable, affordable and safe energy storage technologies that will approach the theoretical limits for electrochemical storage and deliver electrical energy rapidly and efficiently [1]. Two-dimensional (2D) materials [2], including graphene [3], layered transition metal oxides (e.g.,  $\text{MoO}_3$  [4]) and carbides (MXenes –  $\text{Ti}_3\text{C}_2$ ,  $\text{V}_2\text{C}$ ,  $\text{Ti}_2\text{C}$ , etc. [5]) offer a unique opportunity to produce thin or thick films with high volumetric capacitance and energy density, because 2D sheets can be packed denser than activated carbon or metal oxide particles, still providing accessibility for electrolyte. 2D particles can also be printed onto a variety of surfaces and assembled into flexible films without a polymer binder. However, when the lateral dimensions of particles become large and the electrode thickness increases, diffusion may limit the energy storage. To overcome those diffusional limitations, 2D particles can be separated by one- or zero-dimensional particles (e.g., carbon nanotubes or onion-like carbon). By combining double-layer and pseudocapacitive (surface and fast intercalation redox processes) energy storage, it is possible to increase the capacitance well beyond conventional double-layer capacitors. Nitrogen-functionalized graphene, as well as transition metal compounds show capacitance values approaching 500 F/g or 1000 F/cm<sup>3</sup> [5]. Planar architectures that increase the volumetric energy density of electrodes also allow the use of very thin separators or replacing separators by a thin film of gel electrolyte, as no piercing by large particles or sharp tubes/rods is possible. MXenes films having metallic conductivity or highly conducting graphene papers can be used to build current-collector free devices, further increasing the storage per unit of volume or weight.

# PEMFC Cathode Performance and Durability Challenges at Low Platinum Loading

Swami Kumaraguru, Jingxin Zhang, Wenbin Gu, Balsu Lakshmanan and Mark Mathias

*General Motors Fuel Cell Activities  
895 Joslyn Avenue, Pontiac MI 48340  
swami.kumaraguru@gm.com*

Cost of the fuel cell system is one of the biggest challenges towards commercialization of fuel cell electric vehicles. Platinum-based catalysts can contribute a significant percentage of the cost at high production volumes. Platinum loading levels of 0.4 mg<sub>Pt</sub>/cm<sup>2</sup> to 0.2 mg<sub>Pt</sub>/cm<sup>2</sup> for cathode catalyst layer can be achieved by a combination of advances in dispersed Pt catalyst (both Pt and Pt alloy) and efficient use of ionomer in the electro-catalyst layer. Further efforts to reduce Pt loading to <0.1 mg<sub>Pt</sub>/cm<sup>2</sup> requires significant improvements on both performance and durability front. On the performance front, the desired high current density operation (>1.5 A/cm<sup>2</sup>) is severely limited by the presence of local oxygen transport resistance<sup>1-2</sup>. While the mechanism of local oxygen transport resistance is still unclear, it is resistive in nature and the thin ionomer film encapsulating the Pt particles is widely considered to be the source. On the durability front, in addition to traditional degradation mechanisms such as Oswald ripening and non-noble metal dissolution (Co in case of PtCo nanoparticle catalysts), the lower roughness factor (available Pt surface area cm<sup>2</sup><sub>Pt</sub>/cm<sup>2</sup><sub>geometric</sub>) at low loading is very sensitive to contamination from both within the cell<sup>3</sup> and from external sources<sup>4</sup>. Some of the voltage loss from contamination is reversible. The lecture will focus on the above mentioned challenges and provide recommendations for areas of research.

# Challenges and Progress in Developing High Voltage Li-ion Batteries

T. Richard Jow, Jan L. Allen, Joshua L. Allen, Samuel A. Delp, Jeffrey B. Wolfenstine  
U.S. Army Research Laboratory  
2800 Powder Mill Road, Adelphi, MD 20783, U.S.A.  
t.r.jow.civ@mail.mil

The demand for more compact power sources for portable electronic devices and vehicles applications drives the development of more energy dense lithium-ion (Li-ion) batteries beyond what are available today. The use of high voltage cathodes to increase the energy density is one approach that has been actively pursued. The high voltage cathodes considered include 4.7 V spinel  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  (LNMO) and 4.8 V lithium cobalt phosphate  $\text{LiCoPO}_4$  (LCP), versus  $\text{Li/Li}^+$ . However, this approach has encountered difficulties including most notably capacity fading and low coulombic efficiency (CE) in the baseline electrolyte made of  $\text{LiPF}_6$  in alkyl carbonate solvent mixtures. What are the issues? Oxidation of electrolyte at high voltages has been considered as a major one<sup>1,2</sup>. The dissolution of transition metal, highly reactive electrode surfaces at high voltage, and structure instability of the delithiated state of the high voltage cathodes have also been considered<sup>2</sup>.

On the electrolyte front, the use of fluorinated solvents with the expectation that could make the electrolyte more oxidatively stable was pursued<sup>3</sup> for resolving the issues of the LNMO/graphite cells. The use of fluorinated and non-fluorinated additives was also pursued<sup>4,5</sup>. Capacity retention was improved using fluorinated solvents or additives. On the cathode front, a partial substitution of Ni by doping of Fe, Cr and Ga in LNMO,  $\text{LiNi}_{0.5-x}\text{M}_x\text{Mn}_{1.5}\text{O}_4$  ( $\text{M} = \text{Cr, Fe, and Ga, } x=0.08$ ), results in improvement in capacity retention compared to the non-substituted LNMO<sup>6</sup>. The improvement in either electrolyte or electrode itself results in the improvement in capacity retention and CE of LNMO/graphite cells.

For LCP electrode, 0.6 Li utilization could be achieved for each LCP when cycled against Li and faded fast with the capacity retention only at 53% at the 10th cycle in the baseline electrolyte<sup>7</sup>. No improvement in capacity or capacity retention was observed even when the advanced high voltage electrolyte was employed. However, significant improvement in capacity realization and capacity retention were observed by Allen et al.<sup>8</sup> in partial substitution of Co by Fe in LCP even without using high voltage electrolyte. Further improvement was made using high voltage electrolyte<sup>8</sup>.

The above example strongly indicates that improvements in electrode materials and electrolytes need to go hand in hand for the cell level improvements for meeting the needs of tomorrow. This paper will review the recent efforts and present the progresses made in the development of high voltage Li-ion batteries.

Rechargeable lithium batteries have ushered the wireless revolution over last two decades and are now matured to enable green automobiles. However, the growing concern on scarcity and large-scale applications of Li-resources have steered effort to realize sustainable sodium-ion batteries, Na and Fe being abundant and low cost charge-carrier and redox center respectively. However, their performance is limited owing to low operating voltage and sluggish kinetics. Here, we report a hitherto-unknown material with entirely new composition and structure with the first *alluaudite*-type sulfate framework,  $\text{Na}_{2+2x}\text{Fe}_{2-x}(\text{SO}_4)_3$ , registering the highest ever  $\text{Fe}^{3+}/\text{Fe}^{2+}$  redox potential at 3.8 V (vs. Na, and hence 4.1V vs. Li) along with very fast rate kinetics. Rare-metal-free sodium-ion rechargeable battery system compatible with the present lithium-ion battery is now in realistic scope without sacrificing high energy density and high power, and paves way for discovery of new earth-abundant sustainable cathodes for large-scale batteries.

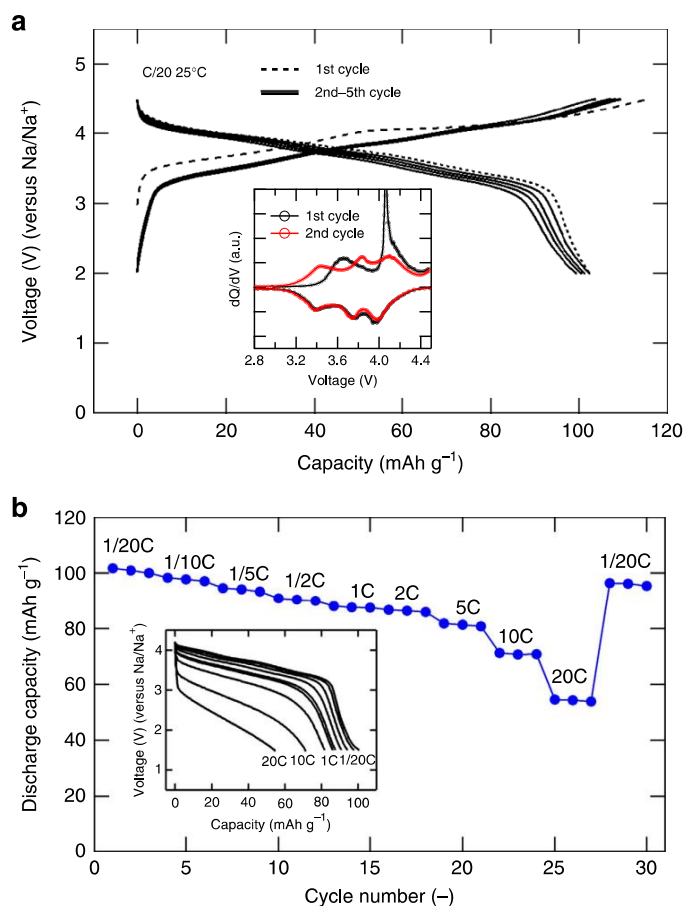

Figure 1. Electrode properties of *Alluaudite*  $\text{Na}_{2+2x}\text{Fe}_{2-x}(\text{SO}_4)_3$

Novel lithium metal polymer solid state batteries with nano C-LiFePO<sub>4</sub> and nano Li<sub>1.2</sub>V<sub>3</sub>O<sub>8</sub> counter-electrodes (average particle size 200 nm) were studied for the first time by in situ SEM and impedance during cycling ( Fig. 1). The kinetics of Li-motion during cycling is analyzed self-consistently together with the electrochemical properties. We show that the cycling life of the nano Li<sub>1.2</sub>V<sub>3</sub>O<sub>8</sub> is limited by the dissolution of the vanadium in the electrolyte, which explains the choice of nano C-LiFePO<sub>4</sub> (1300 cycles at 100% DOD): with this olivine, no dissolution is observed. In combination with lithium metal, at high loading and with a stable SEI an ultrahigh energy density battery was thus newly developed in our laboratory.

## Magnéli Ti<sub>4</sub>O<sub>7</sub> Modified Ceramic Membrane for Electrically-assisted Filtration with Antifouling Property

Ping Geng, Guohua Chen \*

*Department of Chemical and Biomolecular Engineering, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, China*

E-mail address: kechengh@ust.hk

### Abstract

Antifouling tubular Al<sub>2</sub>O<sub>3</sub> microfiltration membranes were successfully developed with a Magnéli Ti<sub>4</sub>O<sub>7</sub> modified inner layer to enhance filtration performance coupling with external electricity. The Magnéli Ti<sub>4</sub>O<sub>7</sub> layer was obtained by first dip-coating a layer of TiO<sub>2</sub> and then reducing this layer at 1050°C in H<sub>2</sub> atmosphere. The fabricated Ti<sub>4</sub>O<sub>7</sub> layer exhibited the conductivity of over 200 S·cm<sup>-1</sup> with particle size of 200 - 300 nm, average pore diameter of 350 nm and contact angle of 0°. The antifouling performance of tubular Ti<sub>4</sub>O<sub>7</sub>/Al<sub>2</sub>O<sub>3</sub> membrane was evaluated through a home-made cross-flow electrically-assisted membrane filtration module for the treatment of three typical feed solutions that are known to foul easily, namely, oily wastewater, humic acid (HA), and bovine serum albumin (BSA). During membrane filtrations, the permeate fluxes of Ti<sub>4</sub>O<sub>7</sub>/Al<sub>2</sub>O<sub>3</sub> composite membranes at around critical electrical potentials could maintain over 90% of their initial values after 1 h, in contrast to the low values obtained with the uncoated Al<sub>2</sub>O<sub>3</sub> membranes, 15.6% for oily wastewater, 62.7% for HA and 41.6% for BSA. Meanwhile, the permeate quality was also improved correspondingly, with oil, HA and BSA rejections increased from 95.8, 2.0 and 18.1% of uncoated Al<sub>2</sub>O<sub>3</sub> membranes to 97.9, 96.2 and 76.1% of Ti<sub>4</sub>O<sub>7</sub>/Al<sub>2</sub>O<sub>3</sub> membranes respectively. The total energy consumed by the electrically-assisted filtration of oily wastewater at around critical electrical potential in 1 h has decreased 44% in comparison with uncoated Al<sub>2</sub>O<sub>3</sub> membrane in term of kW·h per m<sup>3</sup> permeate. For HA and BSA, the total energies also decreased over 57 and 20% compared with corresponding ultra- or nano-filtration membranes, which are commonly used for HA and BSA rejections, at the same average permeate fluxes in 1 h. Therefore, the designed electrically-assisted filtration process with Magnéli Ti<sub>4</sub>O<sub>7</sub> modified membrane provides a promising alternative for ceramic membrane filtrations with antifouling property, good permeate quality and low maintenance cost.

**Keywords:** Electrically-assisted filtration, membrane antifouling, Magnéli titanium sub-oxides, wastewater treatment, bovine serum albumin.

# Palladium-Based Nanomaterials: Synthesis and Electrochemical Applications

Aicheng Chen  
Department of Chemistry, Lakehead University  
955 Oliver Road, Thunder Bay, Ontario P7B 5E1, Canada  
achen@lakeheadu.ca

Palladium (Pd) is well known for its remarkable capacity for hydrogen absorption/adsorption, and is broadly used as a primary catalyst for the low temperature reduction of automobile pollutants, hydrogenation reactions, hydrogen purification, petroleum cracking, and a wide range of electrochemical applications. The main drawback of Pd, much like platinum, is its exorbitant cost. Over the last several years, the price of Pd has increased and is expected to continue to rise as interest in this material expands. Thus, there is an urgent need for the design of advanced catalysts to reduce the amount of noble metals required, while increasing their activity and stability.

In this talk, a number of methods for the synthesis of Pd based nanomaterials, as well as the impacts of their dimensions, morphologies and compositions toward various electrochemical applications are presented and compared. Fabrication strategies primarily include physical synthesis techniques, hydrothermal methods, electrochemical deposition, and other processes, such as electroless deposition, microemulsion, and photochemically assisted synthesis. The chemical and catalytic properties of Pd and Pd-based nanomaterials for electrochemical purposes, including fuel cells, hydrogen purification and storage, gas sensors, biosensors, capacitors and the degradation of pollutants are also discussed. Hydrogen storage remains one of the most challenging prerequisites to overcome toward the realization of a hydrogen based economy. Recent advancements are highlighted regarding palladium based nanomaterials for hydrogen storage, as well as the effects of hydrogen spillover on various adsorbents.

With increasing environmental concerns and the accelerated depletion of fossil fuels, there will be a significant demand for the development of advanced technologies for environmental remediation, as well as for the production of alternative energy conversion and storage devices. In the biomedical sector, the growing need for point of care, real-time quantitative detection and monitoring will drive the emergence of innovative sensing devices and systems. The design and implementation of high-performance Pd-based nanomaterials are anticipated to expand considerably over the next decade.

Compared to other scanning probe microscopy techniques, scanning electrochemical probe microscopy (SEPM) methods suffer seriously from slow image acquisition rates. The timescale of obtaining just one image is often tens of minutes and there are examples where a single image has taken several hours to record. This makes SEPMs impractical for recording more than one or a few snapshots on a particular system and severely limits the amount of dynamic information accessible (activity maps as a function of potential or time), while also raising issues about changes that might occur at the electrode surface (and tip) during such long experiments.

In this contribution, we present two distinct strategies for greatly enhancing the dynamic information content and data throughput in electrochemical imaging experiments. These approaches are illustrated with scanning electrochemical cell microscopy (SECCM, e.g. [1–5]), a powerful multifunctional droplet-based SEPM, but the principles are easily extended to other techniques such as scanning electrochemical microscopy (SECM) and its variants. First, we describe **voltammetric imaging** in which a voltammogram is recorded at every pixel making up an image. Data can be represented as movies (hundreds of frames) of current (over a surface region) at a series of potentials and are highly revealing of subtle variations in electrode activity. We illustrate this concept through studies of outer sphere electron transfer at graphite and graphene, and hydrazine oxidation at platinum. We compare electrochemical images with microscopic and nanoscopic electrode structure in the same area, deduced from atomic force microscopy, Raman microscopy and electron backscatter diffraction. This **multimicroscopy** approach is highly revealing and we show how this general approach provides information on structure-activity that would be lost in both macroscopic measurements and conventional (fixed potential) SEPM.

A second approach is the development of a **high-speed imaging** for the acquisition of a series of high-resolution images at unprecedented rates approaching 4 s per frame. Thus, within less than 10 minutes, > 100 images at different driving forces can be obtained with better resolution (1000 pixels/μm<sup>2</sup>) than in conventional SEPM. This approach is illustrated with studies of model array electrodes, individual carbon nanotubes and catalytic nanoparticles. Together, these studies provide preliminary proof of concept data and a platform for next generation electrochemical imaging. This will see the emergence of SEPMs as truly dynamic techniques, with **electrochemical movies** providing a powerful new way to probe, visualise and understand electrochemical systems.

Some of this work has been partly supported by a European Research Council Advanced Investigator Grant to PRU (ERC-2009-AdG 247143-QUANTIF).

# Ubiquinones: understanding electrochemistry from solution to surface

Yi-Tao Long\*

Key Laboratory for Advanced Materials & Department of Chemistry, East China University of Science and Technology, 130 Meilong Road, Shanghai, 200237, P. R. China.

yitaolong@gmail.com

Quinones are ubiquitous in nature and constitute an important class of natural evolutionary redox molecules. It is well known that quinone fulfill a universal and possibly unique function in electron transfer and energy conservation systems. Ubiquinones are the central cofactors in the enzymatic reaction of the electron-transport system that couples the transfer of electrons to the generation of trans-membrane electrochemical proton gradients that drive the production of adenosine triphosphate in photosynthesis and respiration.

Researches on ubiquinone are not only for better understanding its electrochemical properties, but also for developing ubiquinone-based biomolecular systems to study its biological functions. We have been focusing on ubiquinone from synthesis, electrochemistry and applications and attempt to construct biomimetic systems to mimic the functions of quinone in photosystem II and respiration.<sup>1,2,3</sup>

# An Easily Applicable Green Method for Real Sample Analysis Based on Disposable Gas Sensor

Jyh-Myng Zen

*Department of Chemistry, National Chung Hsing University  
250 Kuo Kuang Road, Taichung, Taiwan  
jmzen@dragon.nchu.edu.tw*

We have developed novel electrochemical gas sensors based on electrochemical deposition of high catalytic metal particles (e.g., Pt, Pd) on screen-printed carbon ultramicroelectrode (SPUME). An efficient mass transfer effect of ultramicroelectrode facilitates for electrochemical reduction of metals. Homogeneous size and distribution of metal nanoparticles can be easily decorated at the surface of carbon ultramicroelectrode without either protective or capped agents. The as-prepared Pt/SPUME was then applied for the development of sensitive nitric oxide, formaldehyde, formic acid and hydrogen peroxide gas sensors can be achieved. The system can also be applied to develop hydroxyl radical, glycerol and triglyceride sensors as well. By using a reaction involving acid and nitrite, in-situ evaluation of NO gas can be carried out in an inert atmosphere and sensing in the gas phase. This new approach was successfully demonstrated for the determination of nitrite in food samples such as sausage and vegetable by standard addition method and the results were compared with the classical spectroscopic method to verify the analytical applicability of the method. These promising analytical performances open new possibilities for easy and selective determination of nitrite and nitric oxide in environmental and biological samples.

## Electrochemistry and Determination of Some Biomedical and Biological Molecules at Carbon – Based Ionic Liquid Crystals Composite Electrodes

Nada F. Atta, Ekram H. El-Ads, Asmaa H. Ibrahim, Youssuf Mohamed, Ahmed Galal

Department of Chemistry, Faculty of Science, Cairo University, 12613 Giza, Egypt, Tel.: +20 0237825266; fax: +20 0235727556, e-mail: [anada@sci.cu.edu.eg](mailto:anada@sci.cu.edu.eg)

The electrochemistry of some organic molecules of biomedical and biological importance is studied using a novel ionic liquid crystals (ILC) carbon composite electrode. ILC are materials that represent green media with remarkable chemical and physical properties. ILC mimic the natural bio-based ionic liquid crystals such as cell membranes structures. Thus a noticeable increase in surface ordering and excellent increase in electrical conductivity resulted in enhanced electron transfer mediation for the electrochemical oxidation process of the studied compounds. Thus, ionic liquid crystal [(1-Butyl-1-methylpiperidinium hexafluorophosphate)] was hybridized with carbon in presence of sodium dodecyl sulfate (ILCMCPE....SDS) for studying the electrochemical behavior of some neurotransmitters and drugs. Cyclic voltammetry, electrochemical impedance spectroscopy and chronoamperometry were used to determine the electrochemical behavior, diffusion coefficients, and electrical characteristics of the electrode. Surface morphology and structure were determined using atomic force microscopy (AFM), field-emission scanning electron microscopy (FE-SEM/EDAX) and surface enhanced Raman spectroscopy (SERS). Examples of studied compounds are Dopamine, Enoxacin, Benazepril hydrochloride, etc. The enhancement of charge transfer was ascertained by the high diffusion coefficients determined at the electrode surface and detection limits in the order of nano-molar quantities were achieved.

Ionic liquid crystals mimic the natural bio-based

ionic liquid crystals such as cell membranes structures in their interactions with drugs.

Cyclic voltammograms (CV) of  $1.0 \times 10^{-3}$  mol L<sup>-1</sup> of EN in B-R buffer pH 7.4 at scan rate 100 mVs<sup>-1</sup> recorded at different working electrodes (bare CP (solid line), CPE....SDS(dotted line), ILMCPE1....SDS (small dashed line) , ILMCPE2....SDS(dashed dotted line) and ILMCPE....SDS(large dashed line).

Mapping local pH changing plays an important role in interfacial reactions such as enzyme reactions, metabolic microbial processes and corrosion science. Solid-state metal-metal oxide electrodes especially iridium (Ir) oxide and antimony (Sb) oxide have been widely used for pH sensing [1]. Mapping of localized pH changes have been demonstrated using scanning electrochemical microscopy (SECM) with micro-sized Sb [2] and Ir microelectrodes [3]. In this contribution, we present atomic force microscopy (AFM) tip-integrated solid-state pH sensors. Commercially available silicon nitride AFM probes were modified with a Sb layer and insulated with Parylene C by polymer vapor deposition. The electrochemical active area was exposed by subsequent focused ion beam (FIB) milling (Fig.1). Calibration of the obtained probes in Tris(hydroxymethyl)aminomethane (Tris) buffer showed approximate a Nernstian slope (53mV/pH) in the range of 2-10 pH. When used for AFM imaging, the topography of the sample surface and local pH changes can be recorded simultaneously. The pH was detected by means of open circuit potential (OCP) against Ag/AgCl reference electrode (Fig. 2).

Fig.2: pH calibration (measurement of open circuit potential against Ag/AgCl reference electrode) in 0.05M Tris buffer.

Fig.1: Scanning electron micrograph of a modified AFM-SECM probe: a) 56° tilted view of electrode area surrounding the tip and b) side view.

To demonstrate the potential of such probes for combined imaging, the pH change during the dissolution of a calcite microcrystal in aqueous solution was investigated as model sample [4]. The microcrystals were embedded in a photoresist (SU-8). First results towards simultaneous detection of pH and topography of calcite microcrystal by AFM-SECM are presented.

During periods of environmental stress, cells produce significant levels of reactive oxygen species (ROS), which damage cell structures and may lead to various pathological conditions. For the analysis of cell physiology in relation to ROS production we report the use of needle-type carbon nanoelectrodes functionalized with platinum as well as Prussian Blue to comprise sensitive amperometric nanosensors for the detection of oxygen<sup>1</sup> and hydrogen peroxide<sup>2</sup>, respectively. The amperometric probes are inserted into single living neurons and HEK cells to measure biologically relevant oxygen species in real time and with minimal perturbation of the cell function due to the small dimensions of the probes.

In order to enhance the sensitivity and versatility of nanobiosensors we show the fabrication of highly sensitive field-effect transistor (FET) probes based on double-barrel carbon electrodes. By depositing polypyrrole (PPy) across the two individually addressable nanoelectrodes a conductive nanojunction is generated. The resulting FET shows excellent sensitivity towards pH changes. Modifying the transistor gate with hexokinase yields a high-sensitivity nanobiosensor for the detection of ATP.

The spear-like shape of the probe allows to position the sensor in proximity to cells and perform real-time chemical analysis with high spatial resolution. We measure the acidification of the cell microenvironment typical of cancer cells. Moreover, the FET nanobiosensors can monitor spatial gradients of ATP released from melanoma cells and cardiomyocytes into the solution and detect the ATP release of a single cell as the response to chemical and physical stimuli.

A glass-type pH electrode is a well-established pH sensor because it has a standard of construction and application. Its remaining disadvantage is mainly due to a solution-containing reference Ag/AgCl electrode. To overcome its problem, there is an interest in the replacement of the Ag/AgCl reference electrode by solid-state reference electrode. Though a variety of considerable efforts were undertaken for years, an all-solid-state pH sensor has not still not commercialized. Here, we applied a differential boron-doped diamond field effect transistor (FET) sensor to realize an all-solid-state pH device. A termination-controlled boron-doped diamond surface was successfully applied for the electrolyte - solution-gate FET (SGFET). To control pH sensitivity, a partially amino-and/or oxygen-terminated, a partially fluorine-terminated, and a hydrogen-terminated diamond SGFET sensor was evaluated. The oxygen-terminated SGFET had pH sensitivity of up to 40 mV/pH, whereas, a fluorine-terminated diamond SGFET had pH sensitivity of down to 4 mV/pH. The characteristics of differential SGFET measurement were studied by using a partially oxygen-terminated SGFET as pH-sensitive FET(ISFET) and a fluorine-terminated SGFET as reference FET(REFET), where a Pt electrode was employed as quasi-reference electrode.

# Disk Shaped Platinum Nanoelectrodes with Unexpected High Surface Area for the Detection of Hydrogen Peroxide

Alberto Citron, Dario Battistel, Carlo Bragato, Daniele Veciani, Salvatore Daniele  
*Department of Molecular Sciences and Nano systems, University Cà Foscari Venice, Calle Larga S.  
Marta 2137, 30123 Venice, Italy  
sig@unive.it*

The unique properties of nanoelectrodes such as high mass transport rate, fast electrochemical responses, rapid potential switching, small RC constants, and the ability to perform measurements in highly resistive solutions, have resulted in their application in a wide range of research areas, including fundamental electrochemical research, neurobiology and single cell studies, as well as in scanning electrochemical microscopy. Reproducible nanoelectrode fabrication with highly controlled electrode geometry can be achieved by pulling metal micro-wires into glass capillaries with the help of a laser pipette puller. In this way, gold, carbon, silver and platinum nanodisk electrodes have been fabricated. Among them, flat platinum or platinized metal/carbon nanoelectrodes have been mostly employed for the detection of reactive nitrogen and oxygen (ROS) species outside and inside a variety of biological cells. For ROS, and in particular for  $\text{H}_2\text{O}_2$ , platinum displays catalytic activity, which can further be enhanced by increasing the real surface area by modification of the geometrical area of the electrode with platinum black or mesoporous platinum films. Interestingly is to note that, by following proper procedures for the modification of the micro- and nano-electrode surface, the higher real surface area does not affect the general above mentioned properties of the small electrodes.

In a recent paper, it has been reported that platinum nanoelectrodes, prepared by the laser puller methodology, have displayed an effective (i.e., real) surface area ( $A_R$ ) much higher than that of the corresponding geometric surface area ( $A_G$ ). This was found by recording cyclic voltammograms in sulfuric acid solutions over the potential window where adsorption of hydrogen and oxygen species occurs. In this way, flat disk shaped platinum nanoelectrodes with a roughness factor ( $R_F = A_R/A_G$ ) as high as 800 has been found. This implies that, with these nanoelectrodes, electrode processes of surface sensitive electroactive species, such as  $\text{H}_2\text{O}_2$ , should be less affected by kinetic hindering.

In this paper we report on the voltammetric behaviour of a series of platinum nanoelectrodes, having radii over the range 15 – 1000 nm, in aqueous solutions containing  $\text{H}_2\text{O}_2$  over a wide concentration range in phosphate buffer media. The disk shaped nanoelectrodes were fabricated by pulling platinum wires into quartz capillaries. These electrodes, investigated in sulphuric acid solutions, displayed unexpected very high surface area ( $R_F$  up to a few thousands), which depended on the disk radius of the nanoelectrode. In particular, it was found that the lower was the electrode radius, the higher the  $R_F$  value. Also, the measurements performed with the nanoelectrodes in aqueous solutions containing  $\text{H}_2\text{O}_2$  in phosphate buffer media showed steady-state voltammetric responses, whose current values were much larger than those predicted on the basis of the geometric surface area and mass transport coefficient of the flat nanoelectrode. Moreover, steady-state currents for both the oxidation and reduction process of  $\text{H}_2\text{O}_2$  were linear over a wide concentration range (0.1mM – 30 mM). These results were explained as due to the higher  $R_F$  value of the nanoelectrodes, which, as for mesoporous or platinised nanoelectrodes, allowed overcoming the kinetic hindering that usually affects the electrode process of  $\text{H}_2\text{O}_2$  at flat platinum surface. Comparative measurements performed either in sulphuric acid or  $\text{H}_2\text{O}_2$  containing aqueous solutions with a classical polished platinum microelectrode 12.5  $\mu\text{m}$  radius supported the above hypothesis.

# Self-Assembled Layer-by-Layer Architectures for Electrochemical Sensors and Biosensors

Christopher M.A. Brett<sup>1</sup>, Madalina M. Barsan<sup>1</sup>, Melinda David<sup>2,3</sup>,  
Monica Florescu<sup>3</sup>

<sup>1</sup>*Department of Chemistry, Faculty of Sciences and Technology, University of Coimbra,  
3004-535 Coimbra, Portugal*

<sup>2</sup>*Facultatea de Fizica, Universitatea din Bucuresti, Magurele 077125, Romania*

<sup>3</sup>*Facultatea de Medicina, Universitatea Transilvania din Brasov,  
Brasov 500019, Romania  
cbrett@ci.uc.pt*

New self-assembled layer-by-layer (LbL) strategies for constructing thin, multilayer electrochemical sensors and biosensors have the potential to improve analyte access to the reaction sites and reduce the diffusion time of the analytes and reaction products, whilst also increasing sensor robustness. Self-assembly by electrostatic attraction as deposition methodology enables organised and stable architectures to be formed with less use of reagents in thin multilayer platforms. Such approaches have yet to be extensively exploited.

In recent work, carbon nanotubes (CNT) and graphene (G), as well as their nitrogen-doped analogues, have been investigated as electrode modifier materials, including in conjunction with redox polymers, as ways to enhance sensor performance. Doping CNT or G with nitrogen can increase the electronic conductivity, as already shown for nitrogen-doped CNT [1] and nitrogen-doped graphene (NG) which can catalyse important biologically-relevant reactions such as enzyme co-factor regeneration [2].

The advantages of the LbL technique for enzyme immobilization in chitosan matrices with CNT or G as electrical bridges have been investigated. Multilayer films containing glucose oxidase (GOx) together with NG dispersed in the biocompatible positively-charged polymer chitosan ( $\text{chit}^+(\text{NG} + \text{GOx})$ ), together with the negatively charged polymer poly(styrene sulfonate),  $\text{PSS}^-$  have been prepared [3], growth monitored by a quartz crystal microbalance and the benefits of nitrogen doping demonstrated. Characterisation of the films was done by cyclic voltammetry, electrochemical impedance spectroscopy and scanning electron microscopy.

The introduction of functional groups into CNT or G, by acidic or basic treatment, increases the specific capacitance and hydrophilicity which in turn influences the multilayer structure. These aspects have been investigated and the best functionalized carbon nanomaterial of the four for construction of a biosensor assembly incorporating glucose oxidase in the positively charged chitosan, with  $\text{PSS}^-$  as negatively charged layer, identified as basic functionalized graphene and acid-functionalised CNT; four bilayers lead to the best biosensor performance. Characterisation by voltammetric techniques and electrochemical impedance after deposition of each bilayer, sensor stability, and comparison with other glucose biosensors was carried out and will be discussed.

# Biocompatible Quantum Dots and Conducting Polymer Nanocomposites in Disease Signalling Biosensors

E.I. Iwuoha

SensorLab, University of Western Cape,  
Department of Chemistry, P. Bag X17, Bellville, Cape Town, 7535, South Africa  
eiwuoha@uwc.ac.za

As biochemical species that indicate the occurrence or the severity of a disease, biomarkers and their detection have become very important in disease therapy. Notwithstanding the benefits of disease treatment with drugs, there is currently an intensified research work world-wide in several fields of study, focused on the development of novel diagnostic methods for early detection and screening of diseases such as cancers. Nanobiosensor systems for the detection of disease biomarkers were constructed at the University of Western Cape SensorLab by the incorporation of biological signaling elements onto biocompatible quantum dots<sup>1,2</sup> and conducting polymer nanocomposites<sup>3-6</sup>. Cancer disease biomarkers sensor to be presented include breast cancer genosensor for human epidermal growth factor receptor-2 (Her2/Neu oncogene) and coeliac disease immunosensor for anti-tissue transglutaminase antibody biomarker for gluten intolerance autoimmune disorder<sup>7</sup>. Other systems are DNA aptamer-based estrogen disrupting affinity sensor, 17 $\beta$ -estradiol receptorsens devised from estrogen receptor  $\alpha$ -recombinant protein (ER- $\alpha$ ) bio-sensitiser and quantum dots genosensors for telomerase reverse transcriptase RNA cancer biomarker. Stress signaling biosensor based on the determination of nitric oxide with a novel arabidopsis flavin monooxygenase<sup>8</sup> bioelectrode is also included in the presentation.

# Nanoparticles Imprinted Polymers (NIP): Speciation of Nanoparticles

Daniel Mandler, Shlomit Kraus, Netta Bruchiel-Spanier, Yamit Pisman, Maria Hitrik  
*Institute of Chemistry, The Hebrew University of Jerusalem*  
*Jerusalem 9190401, Israel*  
[daniel.mandler@mail.huji.ac.il](mailto:daniel.mandler@mail.huji.ac.il)

Nanotoxicity is a new discipline, which requires the development of appropriate tools for determination of nanoobjects such as nanoparticles (NPs). These tools are also crucial for monitoring the interactions between nanoobjects and organisms. These interactions are affected by the core, size, shape, and stabilizing shell of the objects. Hence, speciation of NPs, is becoming of utmost importance. There are known approaches for measuring single particles based on their size. However, simple, miniature and inexpensive sensors for specific NPs detection based on the criteria mentioned above are not available yet.

We will present a new concept for selective recognition of NPs by a polymeric matrix imprinted with the same NPs. This approach can be classified as nanoparticle imprinted polymer (NIP) in analogy to the well-known concept of molecularly imprinted polymers (MIP)] in which the molecular analyte is imprinted in a polymer by polymerization of proper monomers with which it chemically associates. The removal of the template forms complementary cavities capable of selective recognition of the analyte.

We have shown that the NIP concept works in three different systems. The first<sup>1</sup> is based on forming a polyaniline matrix that extracted Au NPs stabilized by citrate to form NIPs, which showed high selectivity based on the size of the NPs. The Au NPs were removed by electrochemical oxidation to form voids that were used as size exclusion matrix. Moreover, we showed that increasing the thickness of the matrix by deposition of multilayers increased the selectivity. The second system<sup>2</sup> was assembled using cellulose acetate in which hydrophobic Au NPs were incorporated. This system showed selectivity based on the thickness of the NPs shell. In the third system<sup>3</sup> a different strategy was used. Namely, the NP were first attached to the surface and then the free area was filled with molecular species, such as oleic acid. The latter wrapped the Au NPs, which were further removed. The reuptake process showed again high selectivity toward Au and Ag NPs of the same size and shape as initially imprinted.

In conclusion, we have developed a new and promising approach for sensing nanoparticles based on their size, structure and shell based on imprinting thin films.

*\*E-mail: [chenlinchi@ntu.edu.tw](mailto:chenlinchi@ntu.edu.tw)*

Modern farming systems, such as plant factory, vertical farming, and information technology-based smart farming, have been developed worldwide recently to cope with food security and safety issues in response to the rapid growth of population (especially in urban areas) and CO<sub>2</sub> emission. This emerging sustainable topic provides electrochemical ion-selective electrodes (ISEs) promising opportunities and niches in future crop cultivation quality control. Viewing cost and size disadvantages of traditional ISEs, our lab has devoted to research and develop novel screen-printed ISEs (SPISEs) technology for real-time or off-line sensing the essential macro-elemental ions (K<sup>+</sup>, Ca<sup>2+</sup>, Mg<sup>2+</sup>, NH<sub>4</sub><sup>+</sup>, NO<sub>3</sub><sup>-</sup>, SO<sub>4</sub><sup>2-</sup>, and PO<sub>4</sub><sup>2-</sup>) for plant growth. In addition to small size, low cost, easy for mass production, and all solid state, our SPISEs also feature a stability-enhancing ion-to-electron transducer (IET) layer in between the ion-selective membrane (ISM) and carbon paste electrode (CPE). Thus, the SPISEs are able to eliminate the potential instability problem (potential drift) in long-term hydroponic nutrient monitoring (Fig. 1). This is because that the IET layer can prevent the formation of a penetrated “water layer” during long-term in-solution monitoring that hinders ion-to-electron transduction between ISM and CPE and decreases ISE sensitivity and selectivity. Meanwhile, the IET layer itself made of an electroactive material can facilitate the ion-to-electron transduction. In this presentation, we will discuss how to select an IET layer material from a list of carbon nanomaterials and conducting polymers, such as amino-modified MWCNT, MWCNT-ester, polypyrrole, polythiophene and poly-o-aminophenol according to water layer test (Fig. 2), charge-transfer resistance estimation, double-layer capacitance measurement, and contact angle characterization. Besides, we will present the sensitivity, selectivity, response time characteristics of a panel of SPISEs based on an ideal poly-o-aminophenol IET layer. We will also show the practical use of SPISEs for hydroponic nutrient sensing in combination with our homemade electronic reader that can transmit the ion-sensing data simultaneously to a smart phone via a Bluetooth module. With this presentation, we will demonstrate how classical ISEs are reshaped for green electrochemistry for tomorrow's society.

*\*[mcastano@micruxfluidic.com](mailto:mcastano@micruxfluidic.com)*

Electrochemical sensors as well as microfluidic platforms are of increasing interest for the development of novel smart analytical tools for Lab-on-a-Chips (LOC) or Point-of-Care (POC) systems. The integration in a single device of microfluidics and electrochemical sensors could pave the way to enhance the miniaturization, portability, automation as well as throughput of multiplexing analysis for several applications.

In this sense, thin-film microtechnologies enable the fabrication of metal-based (micro)electrodes with high precision and resolution in a cost-effective way. Moreover, these technologies are also suitable for the development and integration of microfluidic stages in the same device. Thus, a single microfluidic device with integrated electrochemical sensors could be developed by using an optimized photolithographic process.

In this work, a simple microfluidic chip with integrated (micro)electrodes has been designed, manufactured and evaluated. The new microfluidic electrochemical sensor has been designed for using in a flow injection analysis (FIA) system with a thin-layer approach. The basic layout of the microfluidic sensor is shown in **Figure 1**.

**Figure 1.** Basic layout of the microfluidic electrochemical sensor and AIO platform for using the chips

The full-integrated chips consist of a glass substrate in which the (micro)electrodes are manufactured. Two different electrode approaches were designed; a basic **three-electrode system** (SE) and an **interdigitated microelectrode array** (IDA). A SU-8 resin layer is used for the construction of the microfluidic structure on the glass substrate with the electrodes. Finally, a SU-8 film is used as cover with the inlet/outlet for closing the microfluidic structure, getting the final integrated chip.

The new microfluidic sensor was coupled to a basic flow system by using an innovative multipurpose interface: **All-in-One** (AIO) platform (**Figure 1**). A special add-on, including an inlet and outlet, was developed for integrating the new chip in the FIA system and performing the electrochemical measurements. Thus, the novel thin-layer based flow system enable an excellent control of the fluids through the electrodes, decreasing the use of sample (<20  $\mu$ L) and reagents, but keeping a high sensitivity with very low dead-volume.

The performance of the new microfluidic electrochemical sensors has been evaluated with different phenolic compounds in the FIA system.

# Determination of Fast Electrode Kinetics Using Fourier Transformed Large Amplitude AC Voltammetry

Jie Zhang, Kiran Bano, Si-Xuan Guo and Alan M. Bond

School of Chemistry and Australian Research Council Centre of Excellence for Electromaterials Science,  
Monash University, Clayton, Victoria 3800, Australia  
*Jie.zhang@monash.edu*

Measurement of fast electrode kinetics close to the reversible limit is subject to substantial uncertainties. The concept of using an internal reference for the determination of fast electrode kinetics to minimize the uncertainties has been developed and applied to the Fourier transformed large amplitude AC voltammetry. Kinetic parameters (i.e. electron transfer rate constant,  $k^0$ , and electron transfer coefficient,  $\alpha$ ) do not influence the voltammetric characteristics of a reversible process. Consequently, when the reversible process is employed as an internal reference, predetermined experimental parameters, such as electrode area ( $A$ ), concentration ( $C$ ), diffusion coefficient ( $D$ ) and uncompensated resistance ( $R_u$ ), which often encounter uncertainties, can be reliably and conveniently calibrated based on theory-experiment comparisons. Then, the new  $A$ ,  $C$ ,  $D$  and  $R_u$  values can be used for the determination of electrode kinetics associated the process of interest through theory-experimental comparison exercises with  $k^0$  and  $\alpha$  as the unknown parameters. In this way, the impact of systematic errors in the parameters  $A$ ,  $C$ ,  $D$  and  $R_u$  on the measurement of electrode kinetics near the reversible limit is significantly diminished. Application of this method is demonstrated with respect to electron transfer kinetics associated with oxidation of tetrathiafulvalene (TTF), where the  $\text{TTF}^{0/+}$  process is used as a reversible internal reference for the measurement of the quasi-reversible kinetics of the  $\text{TTF}^{+/2+}$  process. The more generalized concept of an internal reference is also demonstrated by use of the  $\text{Fc}^{0/+}$  ( $\text{Fc}$  = ferrocene) reversible process as an internal reference for measurement of the kinetics of the  $\text{Cc}^{+/0}$  ( $\text{Cc}^+$  = cobaltocenium) process. Via the internal reference approach, heterogeneous charge transfer rate constants of  $0.55 \text{ cm s}^{-1}$  was obtained for the  $\text{TTF}^{+/2+}$  process at a glassy carbon electrode and  $2.7 \text{ cm s}^{-1}$  for the  $\text{Cc}^{+/0}$  one at a carbon fiber microelectrode in acetonitrile (0.1 M  $\text{Bu}_4\text{NPF}_6$ ).

# Patterning of Microelectrode Array with soft lithography for Biological Sensing

Meining Zhang

*Department of Chemistry, Renmin University of China, Beijing 100872, China*

*e-mail mnzhang@ruc.edu.cn*

Biological analysis, environmental monitoring, food safety and disease diagnosis require sensitive, low-cost and multiplex assay. Microelectrode array (MEA) could meet these requirements and has been receiving significant attention because of its advantages such as higher sensitivity (versus macroelectrode) benefited from the enhanced mass transportation, improved signal-to-noise ratio and larger current response (versus microelectrode). So far, the fabrication of regular MEA has been accomplished mainly by depositing an insulating layer on a macroelectrode surface and then making patterned holes in this layer with photolithography, which were often prohibitively expensive and time-consuming. Soft lithography has been proved to be a rapid and cost-effective method to form and transfer patterns and structures. Our group commits to develop various soft lithography for fabricating MEA. We reproducibly fabricated regular Au band MEA with hydrogel etching and proposed a new technique to fabricate reduced graphene oxide (rGO)-based MEA with microtransfer molding. The developed MEA showed a lower detection limit and a larger current density for the detection of biological compounds, such as  $\text{H}_2\text{O}_2$ , dopamine, as compared with the macroscopic electrode.

Figure 1 Schematic illustration of the procedures for fabrication of rGO-based MEA.

whchiang0102@gmail.com

L-cysteine (L-cys), a sulfur containing amino acid, plays a crucial role in regulating the biological activity of certain proteins, peptides and enzymes. Low level of L-cys is related to myriad of diseases, including slow growth in children, lethargy, liver damage, loss of muscle and fat, skin lesions, and weakness. However, current L-cys sensing techniques require intensive pretreatments, purifications with low sensitivity. As a result, developing a relatively easy, selective and sensitive L-cys biosensor in physiological study and clinical diagnosis is highly demanded. Recent works have suggested that heteroatom-doped carbon nanomaterials such as carbon nanotubes (CNTs) and graphenes as novel materials with exceptional properties for electrochemical applications including energy storage and electrochemical sensing. However, current synthesis methods of heteroatom-doped carbon nanomaterials usually involve complicated vacuum systems, making it difficult to enable industrial-scale production. Therefore, the development of a controllable synthesis of heteroatom-doped carbon nanomaterials at atmospheric pressure will lead to important advances on both scientific studies and innovation applications.

Here we demonstrate an atmospheric-pressure, solution-assisted optimized substitution method to produce heteroatom-doped CNTs with varying heteroatoms including B, P, and S. Pristine multi-walled CNTs (MWCNTs) synthesized using a water-assisted chemical vapor deposition (CVD) were used as starting materials. The heteroatom-doped CNTs were then produced by heating the mixture of heteroatom precursor and MWCNTs under argon (Ar) atmosphere from 400 to 1200°C for 1 to 4 hour at atmospheric pressure. Systematic micro Raman intensity ratio ( $I_D/I_G$ ) of the D- and the G- bands indicated the density of defects which induced by heteroatom doping. S-CNTs possess more defects than others and from 2D-band shift, B-CNTs behave more like n-type semiconductor (Fig. 1(a)). Extensive X-ray photoelectron spectroscopy (XPS) indicated that the heteroatoms were successfully doped into the  $sp^2$  graphene lattice of CNTs. The electrical conductance was improved by heteroatom doping (Fig. 2(b)). We found that heteroatom concentrations in the nanotubes could be tuned by controlling the reaction temperature and time. Furthermore, thin-film electrical conductance characterization using a four-point probe method confirmed the electrical conductance of the as-prepared heteroatom-doped CNTs.

Electrochemical characterization shows different performances among B-CNT, P-CNT and S-CNT in Fig. 1(c). The results show that B-CNT possesses the best electrocatalytic ability. It has the lowest overpotential and the highest current density. P-CNT, although does not have an obvious oxidation peak, still shows a relatively large current density. As for S-CNT, the result shows there is nearly no difference between S-CNT and pristine CNT.

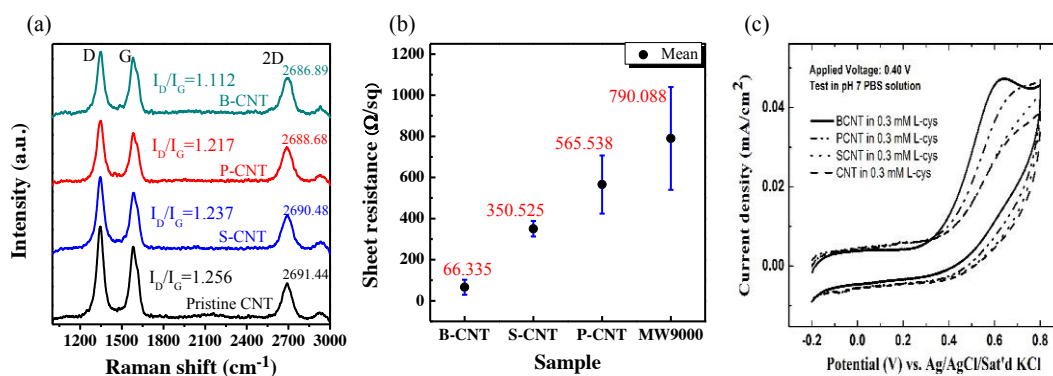

Figure 1. (a) Raman spectra of different atoms doped CNT by solution-assisted substitution method. (b) Resistance of conductive thin-film (PVDF) fabricated by different atoms doped CNT. (c) Cyclic voltammetry of pristine CNT (dash), S-CNT (dot), P-CNT (dash dot dot) and B-CNT (solid).

# In Vivo Electrochemical Assessment of Possible Melatonin Effect on Nitric Oxide Production From Kidneys of Sub-Acute Lead Treated Rats

(fethi.bedioui@chimie-paristech.fr)*

Nitric oxide (NO) is known to be implicated in various renal diseases induced by lead poisoning and recent works have shown the effect of some antioxidants in reducing the toxic effects of lead. Melatonin is attractive for its direct and indirect antioxidant effects; furthermore it is naturally produced in mammals, including humans. Recently, it has been shown that melatonin attenuates the toxic effects of sub-acute lead intoxication in kidneys without altering NO metabolites concentration. This work demonstrates the use of nickel tetrasulfonated phthalocyanine/polyphenol-modified ultramicroelectrodes to monitor in vivo and in situ changes of NO within rat kidneys. NO itself was detected directly and in real-time inside the kidney of lead and melatonin treated rats after induction by L-arginine. The results indicate that NO production decreases in lead treated rats, likewise in co-treated with melatonin rats. In addition, melatonin administration did not affect the production of NO respect to the control. By means of these experiments was verified that melatonin does not alters NO production in kidneys during sub-acute lead intoxication (1).

# **Combined Tyrosinase (A Multi-Potent Enzyme) and Electrodes Modified with nanoparticles for Fast and Highly Sensitive Environmental Monitoring and Medical Diagnostics**

Judith Rishpon, Michal Mossberg  
*Tel-Aviv University*  
*Ramat-Aviv, Israel*  
*Judithri@Tauex.tau.ac.il*

Tyrosinase is a copper-containing enzyme present in plant and animal tissues that catalyzes the production of melanin and other pigments from tyrosine by oxidation. Tyrosinase plays a dominant role in environmental monitoring, food control and medical diagnostic due to its affinity for aromatic compounds nominates.

Dense arrays of self-assembled nanostructures are highly important for the fabrication of high-performance sensors of large surface area. The diphenylalanine (FF), the core recognition motif of the  $\beta$ -amyloid polypeptide, self assembles into discrete nanotubes (Peptide nanotubes, PNTs). Carbon nanotubes (CNTs), were discovered earlier, and are being used extensively for many years in electrochemical biosensors, due to their excellent mechanical and electrical properties and good stability.

We have developed a sensitive and fast biosensor for phenolic compounds using the enzyme Tyrosinase as bio recognition element. Screen printed working electrodes were modified with numerous nano particles (carbon nano tubes and various peptide nano tubes) and we investigated their contribution on the biosensor sensitivity. It was evident from the conducted amperometric experiments, that the modified electrodes had a significantly higher signal, compared to the untreated electrode.

We investigate the inhibition of Tyrosinase using several pesticides. Nano particles modifications were applied on the electrode and studied. In order to monitor environmental contaminants which serve as Tyrosinase inhibitors, we used a microflow system and immobilized Tyrosinase on modified Nanoparticles screen printed electrodes. Our data shows highly sensitive detection (nM range) of parathion, dichlorovos, diazinon and other pesticides.

In addition, a new electrochemical method of detecting and diagnosing melanoma based on melanoma biomarker was developed and its feasibility demonstrated. The method is based on an electrochemical biosensor platform comprised of a special biochip and device, performing a multi-channel amperometric detection of the enzymatic activity of tyrosinase, an enzyme biomarker of melanoma. The newly developed biosensor platform is able to electrochemically detect Tyrosinase activity in fresh biopsy samples. This bioelectrochemical detection method is rapid, yielding results within minutes from biopsy removal. Using "as is" biopsy samples, without pre-treatment, simplifies the process, saves time and reduces cost and labor dramatically.

In conclusion, the Tyrosinase electrochemical biosensors present exciting opportunities for on-site sensitive monitoring of environmental and food contaminants. The cancer diagnostic tools may pave the way towards decentralized clinical applications.

# Selective Proton Pump for Thin Layer Chemical Modulations

Gastón A. Crespo, Majid Ghahraman Afshar and Eric Bakker  
Department of Inorganic and Analytical Chemistry,  
University of Geneva, Quai Ernest-Ansermet 30, CH-1205 Geneva.  
gaston.crespo@unige.ch

We report on a general concept based on a selective electrochemical ion pump used for creating concentration perturbations in thin layer samples (~40  $\mu\text{L}$ ). As a first example, protons are released from a selective polymeric membrane actuator and the resulting pH is assessed potentiometrically with a second membrane placed directly opposite. By applying a constant potential modulation for 30-s, an induced proton concentration of up to 350 mM may be realized. This concept may become an attractive tool for in-situ titrations without the need for sampling, since the thin layer eventually re-equilibrates with the bulk sample. Acid-base titrations of NaOH and  $\text{Na}_2\text{CO}_3$  are demonstrated. The determination of total alkalinity in a river water sample is carried out, giving levels (23.1 mM) comparable to that obtained by standard methods (23.6 mM). The concept may be easily extended to other ions (cations, anions, polyions) and may become attractive for environmental and clinical applications.

Concentration gradients can be modulated in the entire thin layer sample, by applying either an external current or potential to an appropriate ion-transferring element placed (i.e., ion-selective membrane) in contact with the solution. Aiming to demonstrate this idea, we report here on a new fundamental concept that imposes a controlled and selective proton release on a thin layer sample with subsequent potentiometric readout. The thin layer eventually re-equilibrates with a solution of larger volume, allowing one to achieve repeated localized titrations without sampling or volumetric delivery.

Figure 1 schematically shows the thin layer titration concept for a strong acid-base pair (i.e., HCl-NaOH). The electrochemical cell is composed of two key elements, the hydrogen ion actuator and the pH detector. The thin layer solution is delimited by the flat geometry of both elements. The proton pump is a fast diffusive hydrogen ion-selective membrane that acts as a working electrode (WE) in a three-electrode cell with the respective counter (CE) and reference electrode ( $\text{RE}_1$ ) placed outside of the thin layer. The applied potential or the applied current is controlled by a potentiostat/galvanostat that allows the current to flow between the working and the counter electrode while the potential is simultaneously measured between the working and the reference electrode. Opposite to the actuator, a less diffusive pH responsive membrane based on poly(vinylchloride) is located (detector). This membrane is measured at zero-current against a second reference electrode ( $\text{RE}_2$ ) in the outside solution. As expected for a pH probe, the potential readout is linear with pH according to the Nernst equation. This electrochemical configuration combines dynamic and equilibrium electrochemistry bridged by a thin layer sample.

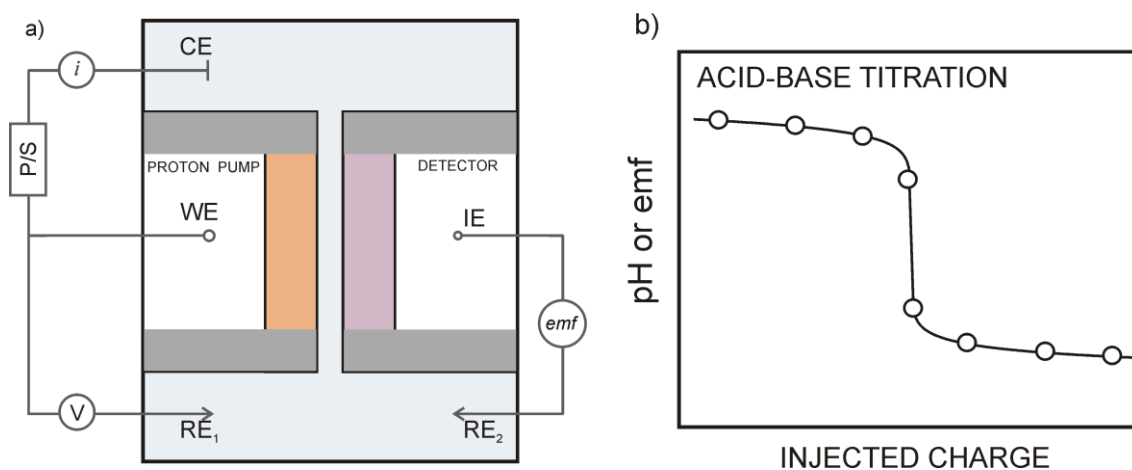

Figure 1 - Schematic illustration of the reported concept. a) Electrochemical cell composed of proton pump and detector proton selective membrane M1 (orange) and M2 (purple), respectively. WE: working electrode, RE: commercial reference electrode, CE: Pt rod, IE: indicator electrode, V: potential reader, i: current reader, P/S: power supply, emf: potentiometer. b) Acid-base titration output signal.

# Gold nanoparticles-modified physically small carbon sensors towards sensitive and selective As(III) detection in aquatic samples

Wycliff Tupiti, Shaneel Chandra

*School of Biological and Chemical Sciences, The University of the South Pacific, Private Mail Bag, Suva  
FIJI*

*chandra\_s@usp.ac.fj*

We present in this work for the first time, new physically small gold nanoparticles-modified carbon electrodes (typically 2  $\mu\text{m}$  diameter and 4  $\mu\text{m}$  axial length) that are capable of rapid and sensitive detection applied towards As(III) detection in aquatic samples have been developed. As is a Group 15 metalloid prevalent in trace levels in the natural environment [1]. In natural waters, it can exist in two different oxidation states depending on the environment and the ratio of As(V) to As(III) in natural water is usually 0.1:1 to 10:1, although As(V) is thermodynamically favored [2].

Arsenic species behave differently in terms of mobility, bioavailability, toxicity, and thus arsenic speciation information is required to understand its biogeochemical cycling and potential toxicity of waters [3]. Its toxic form is As(III) and it is therefore useful to be able to measure this form of the element.

A common challenge in the study of As(III) using conventional carbon-based electrodes is that the species is largely undetected in the absence of surface modification. In this regard, modifications of the carbon surface with gold nanoparticles or gold-based sensors have been previously demonstrated to work successfully. However these have largely focused on using either gold nanoparticles onto conventional glassy carbon electrodes [4], gold nanoparticles with multi-walled carbon nanotubes on glassy carbon electrodes [2], gold wire [3], or gold microwire housed inside polythene tube [5] for instance, which have employed sensing tips greater than those reported in this study.

Physically small carbon electrodes with nanometer dimensions were prepared in our laboratory and characterized prior to and following modification with gold nanoparticles modification were used to selectively detect As(III) in aquatic samples. The electrochemical behaviour of several redox systems including hexamineruthenium(III) chloride, potassium ferricyanide and sulphuric acid was studied to characterize the modified electrodes. The findings from these studies, together with the performance of the electrodes in As(III) detection in aquatic samples will be reported.

# Salt-on-a-chip: Miniaturized Ionic Liquid Systems

Christian Andre Gunawan, Richard Gondosiswanto, Mengchen Ge, Chuan Zhao  
*School of Chemistry, The University of New South Wales*  
*Kensington Campus, Sydney, New South Wales, 2052*  
*christian.gunawan@unsw.edu.au*

Lab-on-a-chip and miniaturized systems have gained significant interest due to dramatic differences in material at the micron-nano scale realm including, material conservation, rapid response or reaction time, and for some cases high product yield.<sup>1,2</sup> Nevertheless, in order to fully exploit their chemistry, solvent volatility problems have to be solved and the reproducibility need to be improved and simplified.<sup>3</sup>

Ionic liquids (ILs) are a class of solvents that typically have negligible vapor pressure with excellent thermal and chemical stability.<sup>4</sup> They have demonstrated applications in many fields of science including electrochemistry. However, the use of ionic liquids in macro scale is often not efficient owing to their poor mass transport as a result of intrinsic high viscosities.

We show in this presentation our effort in fabrication of extremely small ionic liquid drops and microstructures as open, “wall-less” microreactors and sensors on a chip surface that can be part of an electrochemical or spectroscopic system. The micropatterned ionic liquid droplets have been demonstrated as ‘open’ micro-electrochemical cells and photoreactors for microfabrication of metals and charge transfer complexes, substrates for immobilisation of protein forming biological microarray and as membrane-free high-performance amperometric gas sensor array. The results suggest that miniaturised ionic liquid systems can provide a versatile platform for novel applications of ionic liquids.

e-mail: d.arrigan@curtin.edu.au

Electrochemistry at the interface between two immiscible electrolyte solutions (ITIES) provides a simple route to detect non-redox-active ions. Amperometry or voltammetry at the ITIES enables detection of a range of targets, ranging from inorganic ions [1] to biological macromolecules [2]. Miniaturised ITIES, to the microscale and nanoscale [3], have been explored in recent years to achieve an improved sensing and detection capability, e.g. in terms of sensitivity, limits of detection and stability. While the currents are reduced in line with the interface size, current densities are increased due to the enhanced mass transport from radial diffusion. This low current is overcome by use of arrays of micro- or nano-ITIES, which then brings into question design features such as separations between individual elements in the array so as to achieve diffusional independence. In the recent years we have prepared nano-ITIES arrays using electron beam lithography [4] and focused ion-beam milling [5], to create nanopores in membranes at which the ITIES can be formed. FIB offers scope for rapid prototyping of arrays, while EBL is excellent for patterning of large arrays in parallel.

In this work, independent radial diffusion at arrayed nanoITIES was examined. The nanoITIES were formed at nanopores fabricated by FIB milling of silicon nitride (SiN) membranes, which enabled preparation of nanopore array designs with different ratios of pore centre-to-centre distance ( $r_c$ ) and pore radius ( $r_a$ ). These five array designs were used to form arrays of nanoITIES and the transfer of tetrapropylammonium across the water – 1,6-dichlorohexane interface was employed to examine the mass transport effects of the array designs. It was found that the diffusion-limited current for ion transfer increased with the value of  $r_c/r_a$ , reaching a plateau at the theoretical current expected for radial diffusion to an array of non-interacting inlaid interfaces. This indicates that mass transport at the individual nanoITIES was greatly enhanced due to the decreased overlap of diffusion zones at adjacent nanointerfaces. Furthermore, the electroanalytical performance parameters of sensitivity and limit of detection were shown to be at their best when larger  $r_c/r_a$  ( $\geq 56$ ) values were employed. On the basis of these experimental findings, the development of arrayed nanoITIES devices for electrochemical sensing can be improved.

# Cancer Stage Identification by Scanning Electrochemical Microscopy: Investigation of Tyrosinase inside Melanoma Tissues

*Tzu-En Lin, Fernando Cortés-Salazar, Andreas Lesch, Alexandra Bondarenko, and Hubert H. Girault*  
*Ecole Polytechnique Fédérale de Lausanne, Laboratoire d'Electrochimie Physique et Analytique*  
*Station 6, CH-1015 Lausanne, Switzerland*  
*tzu-en.lin@epfl.ch*

Melanoma is one of the most lethal cutaneous malignancies that strikes thousands of people around the world. Indeed, the survival rate depends on the stage of the cancer when it is diagnosed. Therefore, the early diagnosis and unequivocal identification of cancer stages are of high relevance. Since the appearance of melanomas often resembles moles, for its further identification, the microscopic analysis by immunohistochemistry (IHC), fluorescence in situ hybridization (FISH), or comparative genomic hybridization (CGH) are usually performed to confirm the diagnosis[1, 2]. Unfortunately, the read-out of IHC by fluorescent staining, which is one of the most employed methods, could be affected by autofluorescence and photobleaching, leading to wrong diagnosis.

In contrast, electrochemistry has shown to provide efficient tools for the monitoring of malignant tumors by the precise detection of cancer biomarkers, while avoiding common limitations found in optical techniques (*e.g.* sample background, oxygen concentration or light scattering). Scanning electrochemical microscopy (SECM) is a useful scanning tool since it enables the localization of target biomolecules with a high spatial resolution. With this aim, we employed SECM for mapping precisely the presence of the melanoma biomarker tyrosinase. The electrochemical detection of tyrosinase on skin tissue samples from melanoma patients was performed by a sandwich immunoassay readout by SECM (Fig. 1a).

We will demonstrate that we have not only been able to detect the overexpression of tyrosinase on melanoma tissues, but also to differentiate melanoma stages based on the distinct tyrosinase immunopositivity that characterizes each melanoma stage [3]. Implementation and optimization of the proposed approach, as well as, the SECM read out of melanoma tissues will be presented (Fig. 1b). Furthermore, envisioning the possibility of converting SECM as a quick electrochemical screening tool of malignant melanoma, soft linear arrays of microelectrodes have been employed for high throughput analysis. We demonstrate that SECM coupled with immunoassay strategies provides a promising approach for better diagnosis and understanding of the spatial distribution of tyrosinase, and generally it offers great possibilities to study a wider variety of processes on cancer tissues in a reliable manner.

**Fig. 1.** (a) Schematic representation of tyrosinase detection in melanoma by SECM. (b) SECM images of a stage II and III melanoma tissue.

# Nano-Hydrogel Modified Carbon Nanotubes Electrodes for Antioxidant Monitoring in Complex Samples

Andreas Lesch,<sup>a,#</sup> Fernando Cortés-Salazar,<sup>a</sup> Sunny Maye,<sup>a</sup> Véronique Amstutz,<sup>a</sup> Philippe Tacchini,<sup>b</sup> Hubert H. Girault<sup>a</sup>

<sup>a</sup> École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

<sup>b</sup> Edel for Life, Lausanne, Switzerland

# andreas.lesch@epfl.ch

The rapid, reliable and low-cost monitoring of the global antioxidant (AO) content in several biological fluids such as blood bags or beverages is of great interest in the human health sector as well as in the food industry. By transforming excess reactive oxygen species into harmless compounds, AOs can counterbalance oxidative stress conditions. Knowing the AO concentration can provide information about the status of the AO defense system, which is mainly composed of enzymes, metal chelators, drugs and dietary AOs such as ascorbic acid.

One approach to measure directly the AO concentration is by using voltammetric methods. However, biological samples consist usually of complex sample matrices that can influence the electrode surface and consequently the measured signal. Recently, we have demonstrated the batch production of disposable, stand alone carbon nanotubes (CNTs) sensors on polyimide by multi-layer inkjet printing.<sup>[1]</sup> These electrodes showed highly reproducible and homogeneous active electrode areas presenting a quasi-reversible electrochemical behavior adequate for amperometric sensing. Relevant sample information are mathematically extracted from the linear sweep voltammograms and an antioxidant power is determined by using a pseudo-titration concept.<sup>[1]</sup>

Herein, we present a strategy to cover the CNT electrodes with a nanometer thin layer of a polyacrylamide (PA) hydrogel (Fig. 1) which is generated by the simultaneous inkjet printing and UV photopolymerization of self-made inks containing the monomer acrylamide and the cross-linker *N,N'*-methylene-bis-acrylamide in the presence of a photoinitiator and catalyst.<sup>[2]</sup> Within the ink formulation a pre-polymerization step has been introduced to adjust the viscosity of the ink and to enhance the rate of polymerization leading to very stable nano-hydrogel/ CNT electrodes that can be used without pre-treatment. We characterized those PA-modified CNT electrodes optically and electrochemically and applied them for the direct AO monitoring in untreated red wine, fresh orange juice containing pulp and fibers and also in erythrocyte concentrates. In comparison to bare CNT and carbon paste electrodes (CPEs), the nanometric PA coating can compensate for matrix effects showing lower potentials and higher measured currents.

**Figure 1.** Fully inkjet-printed, nano-polyacrylamide hydrogel/CNT electrodes for matrix independent antioxidant monitoring.

Potentiometric sensing utilizing paper- and textile-based microfluidic sampling was applied and evaluated for the determination of clinically ( $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Cl}^-$ ), industrially and environmentally ( $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$  and pH) relevant analytes. In this technological design, calibration solutions and samples were absorbed into sampling substrates (paper, textile). The potentiometric sensors (ion-selective electrodes and reference electrode) were pressed against that substrate while the micro volumes of absorbed liquid closed electric circuit between the two electrodes allowing electrochemical detection of ions. All-solid-state ion-selective electrodes coupled with reference electrode were successfully applied in electrochemical sensing utilizing paper- and textile-based microfluidic sampling. In this method, the sampling substrate acts simultaneously as a sampling unit and as a sample container [1, 2, 3].

Figure 1. Illustration of the potentiometric setup utilizing paper-based (left) and textile-based sampling (right).

As illustrated in Figure 1, the study was done in two sampling modes: paper substrate kept vertical or parallel to the sample surface. Various sampling substrates were investigated for the use in a wide spectrum of applications. Microfluidic sampling was investigated by using paper substrates including three ashless filter papers with different pore size, hospital cotton tissue, dirt-free tissue paper and delicate task wipes. The studied textile substrates included cotton, polyamide, polyester and their blends with elastane. Various samples, such as ground water, moisten soil, food products and artificial serum were used to validate new possibilities for direct chemical analysis of small-volume samples.

# Reduced graphene oxide modified electrodes: from glucose sensing to electrochemical delivery of insulin

Sabine Szunerits

*Institut d'Electronique, de Microélectronique et de Nanotechnologie (CNRS UMR8520), Université Lille 1, Cité Scientifique, avenue Poincaré, BP 60069, 59652 Villeneuve d'Ascq, France*

[Sabine.Szunerits@iri.uni-lille1.fr](mailto:Sabine.Szunerits@iri.uni-lille1.fr)

Diabetes has been assigned next to cancer, cardiovascular and chronic respiratory diseases as the most leading cause of death and disability. A close monitoring of blood glucose concentrations plays a significant role in the diagnostics and prevention of diabetes and tremendous efforts have been put into the development of blood glucose sensors.<sup>1</sup> In this presentation, a special focus will be given on the use of reduced graphene oxide (rGO) nanohybrids for the sensitive sensing of glucose in an enzyme free manner.<sup>2,3</sup> Boronic acid modified rGO as well as electrophoretically formed rGO/Ni(OH)<sub>2</sub> were used for this purpose and their fabrication and sensing characteristics will be discussed.

Moreover, reduced graphene oxide matrixes have shown additionally compliant with efficient insulin loading and release.<sup>4</sup> In type 1 diabetes, absolute deficiency of insulin production results from massive auto-immune destruction of pancreatic beta cells. For this reason, the main therapy consists in delivering exogenous insulin. The treatment methods require numerous daily injections of insulin administered by subcutaneous needle injection, insulin pen and catheters connected to insulin pumps. In this presentation, the advantage of flexible electrodes modified with reduced graphene and loaded with insulin, to electrically trigger insulin release over time will be presented. A special focus will be on the development of insulin-impregnated conductive matrixes and the influence of potential and current on the biological activity of released insulin.

# Highly Sensitive Electrochemical Sensor for Cu (II) Ions Based on Three-dimensional Porous $\text{H}_x\text{TiS}_2$ Nanosheet-polyaniline

Xiaorong Gan, Huimin Zhao\*

Key Laboratory of Industrial Ecology and Environmental Engineering (Ministry of Education, China),  
School of Environmental Science and Technology, Dalian University of Technology, Dalian, 116024,  
China.

e-mail : zhaohuim@dlut.edu.cn

Heavy metal ions as harmful pollutants in the biosphere can result in toxicology and cellular effects even though the human body suffered from chronic exposure<sup>[1]</sup>. Thereinto, abnormal levels of copper ions may greatly damage the liver or kidney of the organisms and cause a series of diseases. Therefore, it is still desirable to develop novel and reliable methods for sensitive and selective assaying of copper ions. Traditional methods for  $\text{Cu}^{2+}$  detection have some limitations such as time-consuming sample pretreatment and sophisticated instrumentation skills. In contrast, electrochemical sensors as emerging technologies showed many advantages for heavy metal ions due to their excellent sensitivity, short analysis time, portability and low cost. Until now, the reported strategies for constructing electrochemical sensors have been developed mainly based on the signal simplification using nanomaterials, enzymes and aptamers etc.

In the study, based on the strong coordination between the nitrogen atoms in polyaniline (PANI) and the transition metal centers of metal dichalcogenides<sup>[2]</sup>, we first synthesized three types of different morphology and structures of hydric titanium disulfide ultrathin ( $\text{H}_x\text{TiS}_2$ ) nanosheet-PANI nanocomposites with different mass ratios of  $\text{H}_x\text{TiS}_2$  nanosheet vs. aniline monomer (1:3.5, 1:1.5 and 1:0.5, respectively), and investigated their electrochemical performances. It was found that the incorporation of  $\text{H}_x\text{TiS}_2$  nanosheets as a suitable substrate can regulate the growth of PANI on the surface of  $\text{H}_x\text{TiS}_2$  nanosheets. As the mass ratio of  $\text{H}_x\text{TiS}_2$  nanosheet vs. aniline monomer was 1:1.5, the obtained nanocomposites showed three-dimensional (3D) porous architectures which were composed of the interconnected  $\text{H}_x\text{TiS}_2$  nanosheets with the help of polymerization reactions of aniline. The nanocomposites modified glass carbon electrode (GCE) showed higher interfacial charge transfer rate, better stability and lower overpotential of  $\text{Cu}^{2+}$  detection than those of other  $\text{H}_x\text{TiS}_2$  nanosheet-PANI nanocomposites. Based on the 3D porous nanocomposites, we developed a novel electrochemical sensor to directly detect trace amount of  $\text{Cu}^{2+}$  by square wave anodic stripping voltammetry (SWASV), and discovered that its high selectivity was contributed to the coordination interaction between  $\text{Cu}^{2+}$  and the nitrogen atoms of the imine moieties in PANI. In addition, the electrochemical sensor exhibited a high sensitivity with a detection limit of 0.7 nM (S/N=3) and a linear range from 25 nM to 5  $\mu\text{M}$  under optimal conditions. The high sensitivity was due to the high conductivity of both PANI and  $\text{H}_x\text{TiS}_2$  nanosheets and the unique 3D porous architectures. The as-formed electrochemical sensor showed good potential in  $\text{Cu}^{2+}$  detection in situ in real water.

# Amplified Electrochemical Analysis of DNA and Proteins

Huangxian Ju

State Key Laboratory of Analytical Chemistry for Life Science, Department of Chemistry, Nanjing University, Nanjing 210093, P. R. China.  
*e-mail address:* hxju@nju.edu.cn

In last two years, we continued to bring nanotechnology and molecular biological technology into the design of electrochemical biosensing strategies, which led to a series of amplified methods for sensitive detection of DNA and protein.

Two porphyrin-encapsulated metal-organic frameworks were used as electrochemical catalytic probes to couple with the designed molecular switches for electrochemical DNA sensing.<sup>1a,b</sup> With gold nanoparticle catalyzed silver deposition and surface circular strand-replacement polymerization, a DNA detection method was proposed.<sup>1c</sup> Two electrochemiluminescent DNA sensors were designed by using carbon nitride nanosheet as emitter for loading of hemin labeled single-stranded DNA and hybridization with a molecular beacon to form hemin/G-quadruplex architecture for signal inhibition.<sup>1d,e</sup> The photoelectrochemical platforms with quantum dot-functionalized porous ZnO nanosheets and catalytic hairpin assembly-programmed porphyrin-DNA complex were also developed for DNA detection.<sup>1f,g</sup> A highly selective detection method for microRNA was presented based on distance-dependent electrochemiluminescence resonance energy transfer between CdTe nanocrystals and Au nanoclusters.<sup>2</sup>

Four electrochemical immunoassay methods for detection small molecules and tumor markers were developed by nanostructure assembly of host-guest linked gold nanorod superstructure,<sup>3a</sup>  $\beta$ -cyclodextrin-functionalized AuPd bimetallic nanoprobe,<sup>3b</sup> platinum nanodendrite functionalized graphene nanosheets,<sup>3c</sup> and nanogold/mesoporous carbon foam-mediated silver.<sup>3d</sup> Three ultrasensitive immunoassay based on electrochemiluminescent quenching of quantum dots along with new quenching mechanisms were designed.<sup>4</sup> More recently, three ratiometric electrochemical proximity assay methods for sensitive one-step protein detection was proposed.<sup>5a,b,c</sup> And an amplified electrochemical immunosensing method for protein biomarker was developed through target-driven triple-binding formation of MNzyme.<sup>5d</sup>

shintani@toki.waseda.jp*

A rapid sensing of pH in solution is of great interest for chemical industry. A glass-type electrode becomes the de facto global standard for pH sensing device, and it is widely used in laboratory and manufacturing process. However, in addition to its instability in fluorine-containing solution such as hydrofluoric acid, an alkaline error is known as serious issue. Furthermore, the glass-type electrode possesses fragile nature and difficulties in miniaturization. Thus, alternative pH electrode is still desirable. A diamond is an excellent candidate since it has wide electrochemical potential window, superior robustness, highly flexible surface modification, and high chemical inactivity. In our previous study, an electrolyte-solution-gate field-effect transistor (SGFET) utilizing a non-doped diamond surface as gate channel was sensitive to various ions, and the diamond termination control can led to the adjustment of pH sensitivity. Here, we proposed a polycrystalline boron-doped diamond channel solution-gate FET. A hydrogen-terminated boron-doped layer was formed on a non-doped diamond film on Si substrate by CVD deposition, and it was employed as SGFET gate channel whose pH sensitivity was down to 10mV/pH. To evaluate pH sensitivity of various diamond terminations, the hydrogen-terminated boron-doped diamond channels were changed to oxygen- termination by UV-ozone treatment, and fluorine-termination by ICPRIE. Fluorine-terminated diamond SGFETs were less-sensitive to pH, whereas, diamond SGFET with partially oxygen-terminated gate surface was sensitive to pH up to 40 mV/pH.

# Investigation of cell aging by analysis of electrolyte decomposition via gas chromatography

Simon Theil, Margret Wohlfahrt-Mehrens  
ZSW-Zentrum für Sonnenenergie- und Wasserstoff-Forschung  
Helmholtzstrasse 8, D-89081 Ulm, Germany  
*simon.theil@zsw-bw.de*

The electrochemical performance of lithium ion batteries can be highly influenced by electrolyte degradation. On the one hand, solvent decomposition is, in case of graphite anodes, intended to build up the SEI. On the other hand it can result in several negative effects, such as pressure build-up because of gaseous decomposition products, loss of lithium due to formation of organic lithium salts, excessive filming on anode and cathode resulting in higher resistance and drying-out of the cell. Most of the decomposition reactions lead to byproducts which are soluble in the electrolyte. By analysing those byproducts it is possible to draw conclusions about the type and quantity of electrolyte decomposition.

For electrolyte analysis we used a Headspace gas chromatography (HS-GC) method due to its high sensitivity to low boiling species and its applicability for LiPF<sub>6</sub> containing electrolyte. The experiments have been performed by aging pouch full cells.

The work mainly focused on two parts of the electrolyte decomposition: Firstly on monitoring the consumption of the well known additive vinylene carbonate (VC), secondly on analysis of the byproducts resulting from solvent decomposition.

The aim was to investigate the type and amount of decomposition during formation as well as during long term aging. Monitoring VC consumption in the first charge of the formation gave information about the build up of the SEI in terms of anode potential, graphite surface and electrolyte composition.

Analysing electrolyte decomposition after storage or long term cycling via gas chromatography could be correlated with several conditions and parameters of the cell. Firstly the influence of electrode balancing and current density, leading to different degrees of lithium plating was investigated. Secondly the effect of the applied potential window, set by the cut-off voltage or changed by switching to different active materials, could be analysed. Furthermore, those experiments have been performed with electrolytes containing different solvent and different amount of additives. The correlation of the change of the electrochemical performance with the electrolyte decomposition led to a deeper understanding of the link between cell aging and electrolyte degradation.

# **Suppression of degradation of lithium ion batteries for $\text{LiFePO}_4\text{@C}$ batteries by nano Si surface modification**

Wenyu Yang, Xiang Chen, Mingzhong Zou, Guiying Zhao, Jiaxin Li, Yingbin Lin, Zhigao Huang\*

College of Physics and Energy, Fujian Normal University, Fujian Provincial Key Laboratory of Quantum Manipulation and New Energy Materials, Fuzhou, 350117, China

**Abstract:** Si nanoparticles are deposited uniformly on the  $\text{LiFePO}_4\text{@C}$  electrode by a spray technique. And the effect of Si incorporation on the electrochemical performances of  $\text{LiFePO}_4\text{@C}$  18650 cylindrical cells is investigated systematically by charge-discharge testing, cyclic voltammograms, AC impedance spectroscopy, respectively. At the same time, the aging and degradation of those cells have been studied. Non-destructive electrochemical methods were used to examine the capacity loss, voltage drop, resistance change, lithium loss, and active material loss during the life testing. The measuring results of the cycle life indicated that the capacity loss was strongly influenced by the rate, temperature, surface modification and discharge states (DOS). Especially, nano Si surface modification suppresses greatly the degradation of those cells. Moreover, the rate, temperature, time, and surface modification dependences of the cycle life were discussed.

# Dealing with Interferences in the Electrochemical Detection of Arsenic – a Complexometric Masking Approach

O.A. Arotiba<sup>a,b</sup>, O.A. Idris<sup>a</sup>, N. Mabuba<sup>a</sup>

<sup>a</sup> *Department of Applied Chemistry, University of Johannesburg, Doornfontein 2028, South Africa*

<sup>b</sup> *Centre for Nanomaterials Science Research, University of Johannesburg, South Africa*  
oarotiba@uj.ac.za

Arsenic, a highly toxic element, has been known to cause many adverse health effects such as dermal changes, gastrointestinal disorder, respiratory impairment, and cancer in human<sup>1</sup>. Contamination of ground water by arsenic has been documented in several countries, where arsenic in drinking water was above the guide line value of the maximum concentration of arsenic in water, which is 10 ppb by the World Health Organisation<sup>2</sup>. The detection of arsenic (III) using stripping voltammetry is a very sensitive, simple and plausible route in comparison to other classical methods such as atomic absorption spectroscopy and inductively couple plasma. However, this electrochemical technique is hampered by few interferences especially copper which gives a false increase in arsenic concentration<sup>3</sup>. In the bid to tackle this copper interference, we present the square wave anodic stripping voltammetric (SWASV) determination of As (III) in the presence of Cu (II) using aqueous ammonia as a complexing agent. Gold nanoparticle (AuNPs) were electrochemically deposited on a glassy carbon electrode (GCE) using cyclic voltammetry to form GCE-AuNP electrode. The modified electrode was electrochemically characterised in  $[\text{Fe}(\text{CN})_6]^{3-/4-}$  redox probe. Arsenic (III) with and without Cu (II) was detected using SWASV. Ammonia solution was then added to the arsenic solution with and without copper while the voltammetric responses were recorded. Our results showed that ammonia was able to selectively mask Cu (II) in the As (III) solution by forming a complex. A detection limit of ca 5 ppb for As (III) in the presence of Cu (II) ion of was calculated. This approach was used for real samples with excellent recovery. This method was further validated by comparing it to inductively coupled plasma technique where a good correlation was observed. Our work such presents a simple and novel way of dealing with interferences in heavy metal sensing using stripping voltammetry.

## Abstract

The process to create graphene nanoribbons (GNRs) from carbon nanotubes (CNTs) can be divided into several categories, including wet chemical methods, physicochemical methods, intercalation exfoliation, catalytic approaches, electrical methods, and so on. In many of the published examples, microwave heating has been shown to dramatically reduce reaction time, increase product yields, and enhance product purities by reducing unwanted side reactions compared with conventional heating methods. [1, 2] Following the trend of eco-conscious, using various methods to reduce the use of chemicals which would pollute the environment in any process is of great interests to scientists. In this study, we demonstrated that the addition of  $\text{KNO}_3$  besides  $\text{KMnO}_4$  can reduce the use of  $\text{H}_2\text{SO}_4$  volume in our microwave-assisted process. Transmission electron microscopy (TEM) were used to examine the morphology and structure of our products. i.e. graphene oxide nanoribbons (GONRs), using much less acid than that in the original recipe. Figure 1 illustrated the core-shell CNT/GONR heterostructure. [1] Furthermore, GONRs were adopted to modify the glassy carbon (GC) electrodes for the electrochemical detection of ascorbic acid (AA), dopamine (DA) and uric acid (UA). After reducing  $\text{H}_2\text{SO}_4$  volume down to 40 %, cyclic voltammograms in Figure 2 showed the similar anodic oxidation currents of AA using GONRs fabricated by the early and green recipes.

*Email: gan-zuei.chang@chem.ox.ac.uk*

Direct formic acid fuel cells (DFAFC) offer the possibility for power generation from oxidation of a liquid fuel, coupled to O<sub>2</sub> reduction.<sup>[1]</sup> The oxidation of formic acid is also of interest for study because it provides a simplified model for methanol oxidation. Platinum has good activity for formic acid oxidation and the mechanism of this reaction has been studied intensively,<sup>[1]</sup> but adsorption of CO (CO<sub>ads</sub>) from dehydration of formic acid on Pt presents a major challenge because CO<sub>ads</sub> poisons surface sites and high overpotentials are needed to activate its oxidative removal. Palladium is considered as an excellent option to replace platinum-based electrocatalysts due to lack of CO<sub>ads</sub> from the dehydration pathway.<sup>[1]</sup> However, a slow deactivation of Pd during formic acid oxidation has been observed by numerous research groups, for example, reference<sup>[2]</sup>. The proposed reasons for deactivation of Pd catalysts include surface poisoning adsorbates such as formate, bicarbonate, carbon dioxide and sulphuric anions.<sup>[3]</sup> Impurities in formic acid have also been suggested as a cause of deactivation of Pd/C by formation of CO<sub>ads</sub> from trace acetic acid, methanol and ethanol in industrial and reagent grade formic acid.<sup>[4]</sup> In this study, we demonstrate the use of a new Attenuated Total Reflectance (ATR)-IR spectroelectrochemical approach<sup>[5]</sup> to investigate electro-oxidation of different purities of formic acids on carbon supported Pd (60 % on XC-72, Premetek). Poisoning by CO was not observed during electrocatalytic oxidation of HPLC grade formic acid. However, IR peaks which have previously been assigned as multi-bonded CO (CO<sub>M</sub>) and hollow-bonded CO (CO<sub>H</sub>) were observed during oxidation of reagent grade formic acid, and CO<sub>ads</sub> was also observed for HPLC grade formic acid 'spiked' with 100 ppm ethanol, methanol or acetic acid. This supports the suggestion that deactivation of Pd/C during formic acid oxidation arises from organic impurities in the fuel.

# Investigation of Single Ni(OH)<sub>2</sub> Nanoparticles: Electrocatalysis and Energy Storage at Ultrafast Mass Transport

Jan Clausmeyer, Justus Masa, Edgar Ventosa, Wolfgang Schuhmann

Analytische Chemie – Center for Electrochemical Sciences (CES), Ruhr-Universität Bochum,  
Universitätsstrasse 150, 44780 Bochum, Germany  
jan.clausmeyer@rub.de

Analysis of single micro- or nanometric objects such as catalytically active nanoparticles reveals information not accessible to classical techniques developed for studying their statistical ensembles. Nanoelectrodes are a versatile tools to perform non-ensemble measurements.<sup>1,2</sup>

Ni(OH)<sub>2</sub> is a well-known catalyst for the oxygen evolution reaction (OER) and also commonly used for energy storage in aqueous batteries. We demonstrate the use of carbon nanoelectrodes for the study of the electrochemical properties of single Ni(OH)<sub>2</sub> nanoparticles. The nanoelectrodes fabricated from pyrolytic decomposition of butane inside of quartz capillaries are tunable in size from 1 nm to several 100 nm.<sup>3,4</sup>

Ni(OH)<sub>2</sub> was electrochemically deposited on the needle-type nanoelectrodes of a few nm in diameter, resulting in the formation of single Ni(OH)<sub>2</sub> nanoparticles.

Compared to classical techniques, this method provides very high mass transport rates, by far exceeding those obtained in rotating disk experiments. Thus, electrode kinetics may be studied at high overpotentials and at current densities as high as 10<sup>4</sup> A cm<sup>-2</sup>. High turnover numbers approaching 1000 s<sup>-1</sup> were found.

For the characterization of battery materials, the diffusion of charge carriers in solution of porous paste electrodes may become the limiting factor and hinder the analysis of the intrinsic properties of the material. Due to the fast mass transport at single nanoparticles electrodes, the influence of diffusion in solution is negligible.

We investigated the pseudo-capacitive contribution to the energy storage in nickel hydroxide, in which case the diffusion in solution becomes more problematic. We found that, even at small particles sizes, the reaction is mainly limited by the diffusion of charge carriers in the bulk of the material, since the pseudo-capacitive contribution appeared to be relatively small and constant for all particle size.

e-mail: g.valenti@unibo.it

Electrochemically generated chemiluminescence (ECL), also called electrochemiluminescence, is a luminescence induced by an electrochemical stimulus.<sup>[1]</sup> As an analytical technique, it possesses several advantages over photoluminescence and chemiluminescence, in particular for (bio)sensor applications.<sup>[2]</sup> The electrochemically-induced way to generate luminescence signal allows to obtain sensors with low background signal and high sensitivity, good temporal and spatial resolution, robustness, versatility, and low cost. The peculiar analytical performances in terms of high detectability of conventional chemiluminescence (CL) are retained and, in addition, the electrochemical trigger of the reaction allows controlling the time and position of light emission from ECL probes. These properties make ECL systems particularly attractive also for microscopy imaging techniques in biological tissue sections or single cells, such as *in situ* hybridization (ISH) and immunohistochemistry (IHC). In this context, the nanostructured materials such as carbon nanotubes (CNTs) and graphene are particularly promising for sensing applications.<sup>[3]</sup>

Here we present the application of optically transparent electrodes based on carbon nanotubes to ECL, demonstrating the electrocatalytic superiority of such materials *vis-à-vis* ITO electrodes. CNTs electrodes are excellent material for ECL application thanks to the very favourable overpotential of amine oxidation that represents the rate-determining step for the signal generation in both research systems and commercial instrumentation. The employ of carbon nanotubes resulted in a ten times higher emission efficiency compared to commercial transparent ITO electrodes. Finally, we demonstrate as a proof of principle that our CNT device can be used for ECL imaging in which micro-beads were used to mimic a real biological sample, such as single cell visualization.

# Ultrasensitive electrochemical sensing of metronidazole using molecularly imprinted polymer decorated hollow nickel nanospheres on carbon nanotubes

Jie Liu, Han Song, Jiang Liu, Lu Zhang, Yingchun Li\*,  
Key Laboratory of Xinjiang Phytomedicine Resources of Ministry of Education, School of  
Pharmacy, Shihezi University, Shihezi, Xinjiang, 832000  
e-mail address: yingchunli@shzu.edu.cn

## Abstract

A novel electrochemical sensor for detecting metronidazole (MNZ) is developed by using hybrid recognition elements of multi-walled carbon nanotubes (MWCNTs) modified with hollow nickel nanospheres (HNNSs) and electropolymerized molecularly imprinted polymer (MIP) on glassy carbon electrodes (GCE). The composite of HNNSs and MWCNTs, serving as the loading platform for MIP film, is introduced for the purpose of double signal-enhancement by raising surface area and electron transport ability, while MIP affords selectivity for specific recognition of MNZ. The morphology of the hybrid materials were observed by scanning electron microscope (SEM) and the properties of the sensor (MIP/HNNSs-MWCNTs/GCE) were examined by cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS). In MNZ determination, MIP/HNNSs-MWCNTs/GCE displayed dynamic linear range from  $2 \times 10^{-15}$  mol L<sup>-1</sup> to  $8.0 \times 10^{-13}$  mol L<sup>-1</sup> with a remarkably low detection limit of  $6.67 \times 10^{-16}$  mol L<sup>-1</sup> (S/N=3), superb selectivity in discriminating MNZ from its structural analogues and good anti-interference ability towards several co-existing substances. The detection limit of MNZ is lower than any reports than we can find. In addition, the sensor showed some favorable features such as simple preparation and good stability. Detection of MNZ in pharmaceutical dosage form and in fish tissue has been successfully carried out without complicated separation treatment.

**Keywords** metronidazole, molecularly imprinted polymer, hollow nickel nanospheres, multi-walled carbon nanotubes, electrochemical sensor

For the efficient generation of electricity out of direct methanol fuel cells (DMFCs), it is essential to eliminate or, at least, to reduce the loss of fuel due to fuel crossing from anodes to cathodes. In this sense, the in situ/on line investigation of fuel cell exhausts would be the first step to solve the problem. The results of this kind of investigation often have limitations with a focus on a single side of the system, therefore, not providing simultaneous detection of chemicals in the fuel cell exhausts of both electrodes. In contrast, this work reports the chemical detection for anode and cathode exhausts using the on-line Nuclear Magnetic Resonance (NMR) system (**Figure 1**) developed for detection of multiple samples at the same time. We used two dimensional <sup>2</sup>H-NMR spectroscopy to observe chemicals present in the liquid anode and cathode exhausts of DMFCs. Our results demonstrate that application of this on-line NMR system can be extended to other chemical systems with multiple chemical flows such as the flow batteries and the combinatorial chemical systems.

**Figure 1.** Schematic of the DMFC on-line NMR system that detects anode & cathode exhausts of a flat type DMFC with a toroid cavity detector (TCD) NMR probe. The inset on the right shows the photograph of the dumbbell-shape central conductor, wrapped in two layers of tubings, of a TCD (left) and the schematic diagram of the central conductor wrapped in two layers of tubing filled with exhausts (right).

# Oxygen Reduction Reactions in Ionic Liquids-Based Mixture Electrolytes for High Performance Rechargeable Li-O<sub>2</sub> Batteries

Asim Khan and Chuan Zhao

School of Chemistry, The University of New South Wales, Sydney, NSW 2052, Australia  
chuan.zhao@unsw.edu.au

Li-O<sub>2</sub> batteries can offer high energy densities at low cost and are promising candidates for future energy storage and energy conversion devices. However, the technology is still at research and development stages and extensive efforts are required to address numerous problems related to discharge/charge cycles to make it commercially successful [1]. In Li-O<sub>2</sub> batteries, the cathode reaction i.e. the oxygen reduction reaction (ORR) is of a great importance and is greatly influenced by the type of electrocatalysts and electrolytes [2]. The nature of electrolyte plays a critical role in the performance/cycle life of Li-O<sub>2</sub> cell. Decomposition of electrolytes by the attack of reactive reduction products leads to the formation of lithium alkylcarbonates and lithium carbonate that greatly reduces the performance/cycle life of Li-O<sub>2</sub> batteries.

Because of their unique properties like non-volatility, non-flammability, thermal stability and good electrochemical stability, ionic liquids have been considered as an electrolyte for Li-O<sub>2</sub> batteries. The ORR has been studied in a range of aprotic and protic ionic liquids [2, 3] as well as in organic solvents such as dimethyl sulfoxide (DMSO), acetonitrile, and dimethyl formamide (DMF) [4]. However, there are very few studies have been carried out for ORR in ionic liquids based mixed electrolytes. The addition of ionic liquids into aprotic organic solvent can possibly lower the overpotential for the oxidation of discharge products and enhances the stability against the attack of superoxide [5, 6].

In this presentation, the oxygen reduction-oxidation processes are investigated in a range of ionic liquid based mixed electrolytes in the presence and absence of Li<sup>+</sup>. Compared to pure organic electrolytes, the ionic liquid based mixed electrolytes exhibit higher conductivity, diffusion and oxygen solubility. Cyclic voltammetry results show that the mixed electrolyte had better retention of cathodic current after several cycles than the pure organic electrolytes. The results show that both cations and anions of ionic liquids have significant effect on ORR mechanism, and the optimized mixed electrolyte can result in improved cell cycling performance.

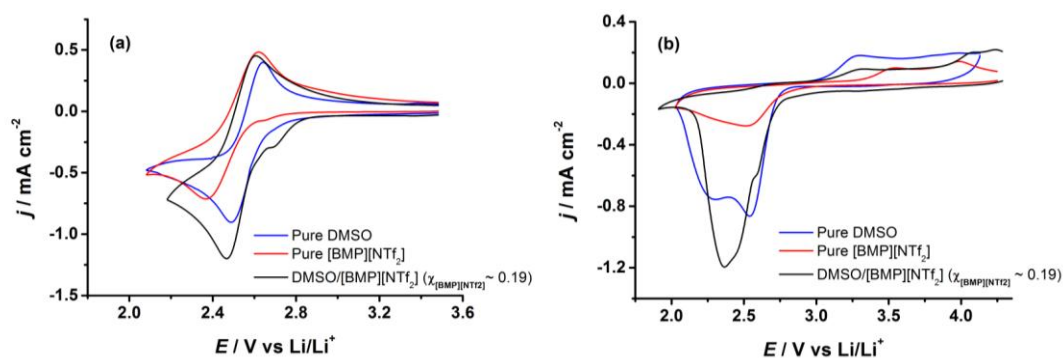

Figure 1: Cyclic voltammograms of ORR on Au electrode in different electrolytes (a) in the presence of 0.1 M TBAPF<sub>6</sub> and (b) in the presence of 0.25 M LiNTf<sub>2</sub>. Scan rate 0.1 V s<sup>-1</sup>.

<sup>4</sup>Yüzüncü Yıl University, Faculty of Science, Department of Analytical Chemistry, 65080 Van, Turkey

keskinertugrul@hotmail.com

The electrochemical analysis of biomolecules has been intensively investigated in recent years. Among these biomolecules, norepinephrine (NE, 4,5- $\beta$ -trihydroxy phenethylamine), also called noradrenaline, is a catecholamine with multiple roles including those as an endogenous hormone secreted by the adrenal medulla and a neurotransmitter in the central nervous system. Medically it is used in those with severe hypotension. It does this by increasing vascular tone (tension of vascular smooth muscle) through  $\alpha$ -adrenergic receptor activation. On the other hand, it is a drug belonging to the stimulants that are on the World Anti-Doping Agency's 2005 Prohibited List. Owing to its important effects in human system, its illegal use by athletes and its therapeutic use, the novel and perspective analytical methods providing rapid, sensitive and reliable detection and determination of NE are important for medical diagnostic tests, for industrial quality control or for doping controls. Its electrochemical detection has been the focus of research for electroanalytical scientists and neurochemists, and some modified electrodes have been used to determine NE [1-3].

This work aims to throw a more light upon its redox behavior at surface of boron doped diamond electrode without any modification by using cyclic and adsorptive stripping voltammetry and to establish a methodology for its rapid determination. The cyclic voltammogram in Britton-Robinson buffer, pH 2.0 showed a couple of redox peaks with the potential value of the anodic and the cathodic (reverse) peaks of +0.852 and +0.174 V (vs. Ag/AgCl), respectively. The experimental conditions affecting the adsorptive stripping behavior were studied in terms of pH of various supporting electrolyte, accumulation variables and square-wave parameters by means of pulse voltammetric techniques due to the well-resolved signal. Using square-wave stripping mode, the compound yielded a well-defined voltammetric response in Britton-Robinson buffer, pH 2.0 at +0.835 V (vs. Ag/AgCl) (a pre-concentration step being carried out at open-circuit condition for 60 s). A linear calibration graph was obtained in the concentration range of 1 to 40  $\mu\text{g mL}^{-1}$  ( $4.9 \times 10^{-6} \text{ M} - 2.0 \times 10^{-4} \text{ M}$ ). A detection limit of 0.254  $\mu\text{g mL}^{-1}$  ( $1.2 \times 10^{-6} \text{ M}$ ) and relative standard deviation of 2.6% for a concentration level of 10  $\mu\text{g mL}^{-1}$  (n: 12) were calculated. As an example, the practical applicability of the proposed method was tested for the determination of this compound in a commercially available ampoule sample which contains NE acid tartrate. The results obtained were statistically analyzed and compared with those obtained by applying the high-performance liquid chromatographic method with diode-array detection.

# Synthesis of Short or Holey Graphene Oxide Nanoribbons for the Electrochemical Detection of Biomarkers

Chia-Liang Sun<sup>1\*</sup>, Chun-Hao Su<sup>1</sup>, Jhing-Jhou Wu<sup>1</sup>, and Chen-Fu Pan<sup>1</sup>

<sup>1</sup> *Department of Chemical and Materials Engineering, Chang Gung University,  
Kwei-Shan, Tao-Yuan 333, Taiwan*

*\*E-mail address: sunchialiang@gmail.com*

In the first part of this presentation, we plan to demonstrate the microwave-assisted synthesis of short graphene oxide nanoribbons (GONRs) through unzipping cut multiwalled carbon nanotubes (MWCNTs). [1, 2] Transmission electron microscopy and dynamic light scattering spectroscopy were used to examine the length, size, and morphology, i.e. unzipping level, of our various products. The nanotube core and nanoribbon shell can be observed from short GONRs via a modified unzipping recipe. Then the short GONRs were adopted to modify the glassy carbon electrode for the electrochemical detection of ascorbic acid (AA), uric acid (UA), and dopamine (DA). Compared to other nanomaterials, cyclic voltammograms of short GONRs show higher anodic oxidation currents for AA, UA, and DA. The detection limits of three analytes are 26, 98, and 24 nM, respectively, in amperometric current-time measurements. Especially, the sensitivity for DA is improved to be  $40.86 \mu\text{A} \mu\text{M}^{-1} \text{cm}^{-2}$ . The improved detection signals are due to the increased active sites of the open ends of short GONRs. Moreover, the width side of short GONRs could be more active than their length side. All above-mentioned results reveal that the short GONRs can provide a novel platform for electrochemically biomarker detection of Parkinson's disease. In the second part of this presentation, we plan to demonstrate the synthesis of holey GONRs (hGONRs) with the help of a facile thermal treatment. The improved electrochemical properties of hGONRs will be shown and correlated with their morphologies.

# Fabrication of Electrochemical Biosensor by Using Peptide as a New Kind of Recognition Element

Hao Li<sup>a</sup>, Yue Huang<sup>a</sup>, Luming Wei<sup>a</sup>, Weiwei Li<sup>a</sup>, Xiaoli Zhu<sup>b</sup>, Genxi Li<sup>a,b,\*</sup>

(<sup>a</sup> State Key Laboratory of Pharmaceutical Biotechnology, Department of Biochemistry, Nanjing University, Nanjing, 210093; <sup>b</sup> Laboratory of Biosensing Technology, School of Life Sciences, Shanghai University, Shanghai 200444; E-mail: genxili@nju.edu.cn)

Over the last decade, artificially synthesized targeting ligands, particularly aptamer, have gradually evolved into a powerful tool of molecular recognition, not inferior to the biologically generated antibodies. In the meantime, it should be noted that short functional peptide, frequently acting as therapeutic and biomedical agent, can target many kinds of protein-ligand interactions, thus peptide may also be used as recognition element for the development of electrochemical biosensors. Therefore, some functional peptides have been recently constructed and employed in the lab of the authors, through electrode surface self-assembly, to form sensitive biosensing interfaces for protein detection. In these biosensor designs, the peptide motifs of protein recognition, metal ion coordination, and several other biochemical functions have been assembled and combined to construct multi-functional peptide-based probes, while some protein sensing interfaces have been preliminarily optimized to suit the need of clinical detection of disease marker proteins.

As is well known, peptide is the structural element composing the complex functional structure of a protein molecule. To some extent, peptide also possesses the chemical and conformational diversity of a protein molecule, which enables interaction with a myriad of partners ranging from bio-active small molecules, biological macromolecules, all the way to synthesized nanomaterial or even macroscopic surfaces of metal and glasses. Among these interactions, many a peptide-ligand recognition is potentially exploitable for biosensor design. On the one hand, the many protein-targeting peptide sequences screened out and rationally designed during the last few decades can provide a rich reservoir for the design of sensing probes for protein detection. On the other, peptides having molecular partners beyond protein molecules can furnish these protein-targeting peptide probes with more diverse biosensing functions such as signal conversion and amplified signal readout. Therefore, many peptide-based biosensing interfaces have been designed and fabricated in our lab for the electrochemical detection of different types of protein targets. For instance, based on the "host-guest" inclusion of peptide side chain groups into synthetic macrocyclic host, the coordination of metal ion by short 3-mer peptides, and the bioconjugation of therapeutic function groups to peptides, several electrochemical biosensors have been developed for the detection of disease markers in cancer of various origins, as well as in Alzheimer's disease. Furthermore, by conjugating the small-molecule peptide probe with some kinds of macromolecules, the modified peptide probe can be used together with the original probe to electrochemically study the relationship between the number of nitrated amino acids and functional state of the target proteins.

In the above biosensor designs, electrochemical techniques can control and fine-tune the micro-environment of the peptide probes on the sensing interfaces, such as the oxidative/reductive status, ion strength near the surface layer, which in turn determines the peptide-ligand interactions of the biosensing process. These electrochemically controlled biosensing peptides and sensitive interfaces have extended the scope of design for protein biosensor and its application in clinical protein detection. Taking the chance to participate in the great event of the 66th ISE Annual Meeting, the authors would like to share the ideas of the typical strategies for the fabrication of some electrochemical biosensors by using peptide as a new kind of recognition element.

# Study of the Electrochemical oxidation of Dissolved Carbon monoxide in Acidic and Alkaline electrolytes by Using and Fabricated Au-Microelectrode

Robin Wang, Trav Huang, Andrew S. Lin

*Department of Chemical and Materials Engineering, Chang Gung University,  
Taoyuan, Taiwan  
E-mail: andrew@mail.cgu.edu.tw*

## Abstract

In this study, gold (Au) was used to study the electrochemical oxidation of dissolved carbon monoxide (CO) in acidic or alkaline electrolytes. The experimental results indicate that gold micro-electrode or gold clusters on micro-electrode may measure limiting currents without using rotating disk electrode approaches. Microelectrode is defined as having at least one dimension of an electrode in the micrometers and the characteristics of these electrodes is as following (i) small amounts of current (ii) small electrode area and (iii) measurements of limiting currents without forced convections.

The electrochemical oxidation of dissolved carbon monoxide (CO) on Au-RDE is mainly diffusion-controlled processes at the potentials greater than 0.6 V (vs. RHE) in acidic electrolyte and 0 V (vs. RHE) in alkaline electrolyte, respectively. Fabricated Au-microelectrode is used to study the rates of mass transfer of the dissolved carbon monoxide (CO) electro-catalysis in acidic and alkaline system. The limiting currents of microelectrode measurements indicated the forced convection phenomena with no rotating disk electrode needed. The onset potentials of gold micro-electrode indicate the electro-catalytic effects on the electrochemical oxidation of dissolved CO.

Fig.1 Cyclic voltammetry of solution phase CO oxidation on rotating gold disk electrode in 1M KOH (left) and 1M HClO<sub>4</sub> (right) in various rotating speeds (400 to 2500 rpm) with sweep rate of 20 mV/s.

Detection and quantification of phosphorus is needed in environmental, medical, and agricultural fields in addition to food, drink, and drug, while the method is limited to the visible spectroscopy in combination with a chemical reaction between phosphorus and molybdenum, *i.e.*, molybdenum blue method. A electrochemical sensor would be one of the possible options for phosphorus sensing, and some literatures [1,2] has mentioned oxide catalysts to quantify phosphorus concentration in aqueous solutions by measuring redox potential or oxidation current, although it is still needed to improve the sensitivity, selectivity, concentration range, and response time. In this work, the development of a novel catalyst for electrochemical sensing of phosphorus was done, in which the target is hydrogen phosphate ions, HPO<sub>4</sub><sup>2-</sup>. For this purpose, we focused on RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> mixed oxides which can be prepared by thermal decomposition of a precursor solution and can be changed in crystallographic structure and composition by modifying the metal contents in the precursor solution and thermal decomposition temperature. The results present very unique properties on electrochemical catalytic activity of the mixed oxide to HPO<sub>4</sub><sup>2-</sup> and an excellent possibility for the novel material of the detecting electrode for electrochemical hydrogen phosphate sensors.

RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> mixed oxides were prepared by thermal decomposition of precursor solutions containing Ru (III) and Ta (V). The Ru mole ratio was changed from 30 mol% to 80 mol% and thermal decomposition was carried out at a temperature from 260 °C to 500 °C. The characterization of the coatings was done with XRD and SEM. Electrochemical measurements by cyclic voltammetry and chronoamperometry were performed using a conventional three-electrode cell and KCl solutions with or without various concentration of HPO<sub>4</sub><sup>2-</sup>.

XRD and SEM measurements revealed that the crystallographic structure of RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> mixed oxides became amorphous with decreasing thermal decomposition temperature and lowering Ru mole ratio. Cyclic voltammograms indicated that HPO<sub>4</sub><sup>2-</sup> was oxidized at 0.8 V or more vs. KCl sat. Ag/AgCl followed by the diffusion-limited current which increased with the concentration of HPO<sub>4</sub><sup>2-</sup>, so that the oxidation of HPO<sub>4</sub><sup>2-</sup> occurs on RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> coatings. The oxidation current was also examined by chronoamperometry, and the data at different concentrations of HPO<sub>4</sub><sup>2-</sup> are summarized in Fig. 1. It is clear that the oxidation current density is linear to the concentration, in which the linear region is found in a wide range from 10<sup>-6</sup> mol/L to 10<sup>-2</sup> mol/L. This result is quite important, because RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> catalyst can present the constant sensitivity which is independent of the concentration range, even though chloride ions, a typical ion of specific absorption, are contained in the test solution. Therefore, this work has proven that HPO<sub>4</sub><sup>2-</sup> can be electrochemically detected and quantified with the novel electrocatalyst, RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub>, prepared by thermal decomposition.

In this paper, more detailed results on the effects of the composition and thermal decomposition temperature in oxide preparation on the catalytic activity to HPO<sub>4</sub><sup>2-</sup> will be presented.

Figure.1 Relationship between the HPO<sub>4</sub><sup>2-</sup> concentration and the oxidation current density measured with RuO<sub>2</sub>-Ta<sub>2</sub>O<sub>5</sub> catalysts.

# Normalised Sampled-Current Voltammetry at Microdisc Electrodes: Kinetic Information from Pseudo Steady State to Steady State Voltammetry

Samuel C. Perry, Guy Denuault  
University of Southampton  
University Road, Southampton SO17 1BJ, UK  
scp2g08@soton.ac.uk

In sampled-current voltammetry (SCV), current transients acquired after stepping the potential along the redox wave of interest are sampled at a fixed time to produce a sigmoidal current-potential curve akin to a pseudo steady state voltammogram. Repeating the sampling for different times yields a family of SCVs. In this way, multiple SCVs can be recorded from the same collection of current transients.

The concept is used to describe the current-time-potential relationship at planar electrodes, but is rarely employed as an electroanalytical method except in normal pulse voltammetry, where the chronoamperograms are sampled once to produce a single voltammogram. Here we combine the unique properties of microdisc electrodes with SCV (MSCV) and report a simple protocol to analyse and compare the MSCVs irrespective of sampling time. This is particularly useful for microelectrodes where cyclic voltammograms change shape as the mass transport regime evolves from planar diffusion at short times to hemispherical diffusion at long times. We also combine MSCV with a conditioning waveform to produce voltammograms where each data point is recorded with the same electrode history and demonstrate that the waveform is crucial to obtaining reliable MSCVs below 100 ms.

To facilitate qualitative analysis of the voltammograms, we convert the current-potential data recorded at different time scales into a unique sigmoidal curve by normalising MSCVs by the theoretical diffusion controlled current<sup>1</sup>, which clearly highlights kinetic complications. To qualitatively model the MSCVs, we derive an analytical expression which accounts for the diffusion regime and kinetic parameters. The procedure is validated with the reduction of  $[\text{Ru}(\text{NH}_3)_6]^{3+}$ , a model one electron outer sphere process, and applied to the derivation of the kinetic parameters for the reduction of  $\text{Fe}^{3+}$  and ferricyanide on Pt microdiscs<sup>2</sup>. The methodology reported here is easily implemented on computer controlled electrochemical workstations as a new electroanalytical method to exploit the unique properties of microelectrodes, in particular at short times.

Figure 1: Sampled current voltammograms at a microdisc electrode (MSCV) showing the increase in current as the sampling time is shortened (left) and the kinetics effects revealed by the normalisation procedure (right)<sup>2</sup>.

# The Modification of Screen-printed Carbon Electrodes with Polymerized Ionic Liquid Composites for Chemical Analysis

Sheng-Huang Wu, Yi-Jhong Chen, Yi-Yu Chen, Yang Hsiao, Guor-Tzo Wei

*Department of Chemistry and Biochemistry, National Chung Cheng University*

*168 Univ. Rd., Min-Hsiung, Chiayi 62102, TAIWAN*

*chegtwtw@ccu.edu.tw*

The use of ionic liquids for electrode modification has been widely reported recently<sup>1</sup>. Ionic liquids are good media to dissolve/suspense nanomaterials<sup>2-3</sup>. In this study, we used ionic liquids to immobilize nano-materials on the electrode surface and form a disposable composite-material modified screen-printed carbon electrode for electrochemical analysis. With the conductive ability of ionic liquids, it can effectively enhance the electron transfer and improve the detection sensitivity. The results demonstrate the potential of ionic liquid as the platform of chemical modify electrode.

In the first example of the study, multi-walled carbon nanotubes (MWCNT) and graphene (reduced graphene oxide, RGO) were added to the mixture of two ionic liquid monomers ([C<sub>4</sub>VIM][PF<sub>6</sub>] and [C<sub>9</sub>(VIM)<sub>2</sub>][PF<sub>6</sub>]<sub>2</sub>), and dropped coating this mixture on the surface of screen printed carbon electrode (SPCE). With thermal polymerized, nano-carbon ionic liquid composite modified SPCEs (CNT-PIL-SPCE and RGO-PIL-SPCE) were created. Due to the large surface area of CNT and RGO, the currents of CNT-PIL-SPCE and RGO-PIL-SPCE are greater than bare SPCE. In addition, the reactive potential is lower. Due to the robustness of the electrode, we were able to use flow injection analysis (FIA) for the analysis of adenine and guanine with CNT-PIL-SPCE. The detection limits are 1.93  $\mu$ M and 1.37  $\mu$ M (S/N=3) for adenine and guanine, respectively. RGO-PIL-SPCE was used for the determination of 2-mercaptoethanol (2-ME) and 3-Mercaptopropionic acid (3-MPA), the detection limits are 8.03  $\mu$ M and 1.22  $\mu$ M (S/N=3) for 2-ME and 3-MPA, respectively.

In the second example of the study, Ag nanoparticles were incorporated into the poly-ionic liquid modified screen printed carbon electrode to form an AgNP-PIL-SPCE electrode. We used cyclic nitramine explosive, HMX (Octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine), as a model compound to demonstrate that AgNP-PIL-SPCE electrode has catalytic activity of non-aromatic explosive. Since AgNP-PIL-SPCE has high stability, we were able to employ flow injection analysis for HMX analysis. The detection limit of HMX is about 10  $\mu$ M (S/N=3).

# An in-situ Microelectrode Study of the Sea Surface Microlayer: Experimental and Theoretical Challenges

Guy Denuault, Ana Cristina Perdomo Marin  
University of Southampton  
University Road, Southampton SO17 1BJ, UK  
gd@soton.ac.uk

We will describe and discuss experimental results obtained with microelectrodes and scanning electrochemical microscopy (SECM) during an investigation of the sea surface microlayer (SML), a complex medium at the interface between bulk sea water and the atmosphere. Although the SML plays a key role in ocean-atmosphere exchanges, its thickness, structure and composition are still poorly understood, primarily because appropriate sampling and analytical methods are still lacking. While some defined the SML as the upper 1 mm of the surface oceans others determined its thickness to be circa 50  $\mu\text{m}$ . In some instances it is described as a multilayer stratified medium, in others it is considered as a continuous medium. Its precise composition is particularly difficult to determine but it is known to consist of a mixture of inorganic (various salts including heavy metals, dust particulates, etc...), organic (natural lipids, fatty acids) and biological (extra cellular matrix, bacteria, microalgae, etc...) matter. As a result, its properties, e.g. viscosity, pH, oxygen and  $\text{CO}_2$  solubility, are thought to vary across the layer.

Our aim is to develop a new analytical approach to study the SML and since sampling of the medium is a challenge we opted to employ microelectrodes and SECM to perform in-situ electroanalytical measurements. To facilitate the interpretation of results during the development of the analytical protocol, we carried out experiments with a range of synthetic SML and used redox mediators to probe the properties of the medium. We used the SECM to position the microelectrode tip at various positions within and below the SML and performed voltammetry and chronoamperometry at each location. Approach curves were also recorded. Exploiting the properties of microdisc electrodes, chronoamperograms were analysed to simultaneously extract the diffusion coefficient<sup>1</sup> and concentration of the redox mediator at each tip location. Using nanostructured PdH microdisc electrodes developed in our group<sup>2-4</sup> attempts were also made to record pH transients at different depths when varying the partial pressure of  $\text{CO}_2$  above the SML.

This presentation will describe the experimental and theoretical challenges encountered during the study.

# Electrochemical Determination of Bisphenol A at Conducting Poly(diallyldimethylammonium chloride) Film-Modified Preanodized Screen-Printed Carbon Electrodes

Yen Hua Liao, Ya-Ling Su, Shu-Hua Cheng\*

*Department of Applied Chemistry, National Chi Nan University,*

*Nantou Hsien 54561, Taiwan*

[shcheng@ncnu.edu.tw](mailto:shcheng@ncnu.edu.tw)

Bisphenol A (BPA) is widely known as a toxic endocrine-disrupting compound. In this study, a selective electrochemical sensor based on medium exchange procedure was developed for the determination of BPA. A conducting film-modified preanodized screen-printed carbon electrode (SPCE\*) was prepared, using 0.2% poly(diallyldimethylammonium chloride) film (PDDA). The surface characteristics of the obtained electrode were characterized by field emission scanning electron microscopy (FE-SEM), X-ray photoelectron spectroscopy (XPS), Fourier-Transform infrared spectrometer (FTIR), and atomic force microscope (AFM) experiments. The SPCE\*/PDDA contains highly abundant nitrogen functionality, and was found to be hydrophilic to adsorb anion strongly and hence increase the detection sensitivity. The proposed sensor exhibited a linear response to BPA in the range of 1 to 20  $\mu\text{M}$  in pH 9.0 buffer solution under the optimized differential pulse voltammetry (DPV). The method sensitivity and detection limit ( $S/N=3$ ) are 9.15  $\mu\text{A}/\mu\text{M}$  and 0.4  $\mu\text{M}$ , respectively. A simple medium-exchange procedure was developed for the selective determination of BPA in complex real samples by the use of the SPCE\*/PDDA. The recovery of spiked BPA in Tamsui River (Taiwan) and fresh milk samples was studied using standard addition method.

([fethi.bedioui@chimie-paristech.fr](mailto:fethi.bedioui@chimie-paristech.fr))

Small fiber neuropathy is a dysfunction caused by diseases such as type II diabetes and cystic fibrosis. This disease can be detected rapidly using a non-invasive device, Sudoscan<sup>TM</sup> technology (Impeto Medical Inc.). This technology is based on measurements of the electrochemical conductance of the skin *via* the imposition of low amplitude voltages between electrodes applied to the skin and measuring the low current generated. The output measurement is related to the sweat composition associated to glands innervations and their permeability to chloride and proton ions. In order to acquire deeper understanding on the mechanisms occurring at the electrodes and optimize the sensitivity of the instrument, *in vitro* electrochemical experiments were performed in mimetic electrolytic solutions of sweat. The present work was dedicated to the analysis of the electrochemical behavior of different biocompatible stainless steels and, more precisely, their resistance to the pitting corrosion in sweat mimicking electrolyte at pH 7, and using chloride concentrations varying between 36 and 120 mM and carbonate as buffer. Their behavior was compared to that of nickel that was initially used as sensing electrode in the technology and thus serves as reference material. Despite the low chloride concentrations, the corrosion behaviors of stainless steel were markedly different. AISI 430T is not sensitive to chloride concentrations in sweat concentration range so that this stainless steel cannot be used for the Sudoscan<sup>TM</sup> technology. Duplex 2205 and AISI 430 can be good substitutes to 304L as these materials are more sensitive to chloride variations and at lower potentials in comparison to 304L. Among the materials investigated, the best substitute appears to be stainless steel 430

# **‘Nano-impacts’: An Electrochemical Technique for Nanoparticle Sizing in Optically Opaque Solutions**

Her Shuang Toh, Richard G. Compton

Oxford University

Department of Chemistry, Physical and Theoretical Chemistry Laboratory, Oxford University, South Parks Road, Oxford, OX1 3QZ, United Kingdom

her.toh@keble.ox.ac.uk

Typical laser-dependent methods such as nanoparticle tracking analysis (NTA) and dynamic light scattering (DLS) are not able to detect nanoparticles in an optically opaque medium due to scattering or absorption of light. In this talk, the electrochemical technique of ‘nano-impacts’ is used to detect nanoparticles in solution in the presence of high levels of alumina particulates causing a milky white suspension.

Anodic particle coulometry (via ‘nano-impacts’) is a novel technique developed within the last 20 years which works on the basis of recording single nanoparticle-electrode impact events through electrochemistry.<sup>[1]</sup> These events are recorded through the electrochemical signal generated by the redox reaction of the nanoparticle. In this talk, citrate capped silver nanoparticle diffuses under Brownian motion and hits the carbon microelectrode held at a suitable oxidising potential. Thus, the silver nanoparticle is oxidised into silver(I) ions, generating a current ‘spike’ which is observed in the chronoamperogram recorded. Through the use of Faraday’s first law, the size of the nanoparticle can be estimated via Equation 1.<sup>[2-3]</sup>

$$R_{NP} = \sqrt[3]{\frac{3QA_r}{4\pi F\rho}} \quad (1)$$

where  $R_{NP}$  is the nanoparticle radius,  $Q$  is the total charge passed under a single ‘spike’,  $A_r$  is the atomic molecular mass of silver of  $107.9 \text{ g mol}^{-1}$ ,  $F$  is the Faraday constant and  $\rho$  is the density of silver of  $10.5 \times 10^6 \text{ g m}^{-3}$ . Therefore, if the opacity is caused by inert particles, this technique is capable of differentiating between the redox active nanoparticles and the inert particulates.

Using this method, silver nanoparticles were successfully detected and sized in the model opaque medium containing high concentration of alumina particulates. The nanoparticles are sized to be  $13.8 \pm 2.2 \text{ nm}$  via the electrochemical method and it compares well with the results obtained transmission electron microscopy (TEM) ( $14.6 \pm 2.1 \text{ nm}$ ), an ex situ method for nanoparticle size determination. Therefore, the ability to use the ‘nano-impacts’ method in media unmeasurable to competitor techniques confers a significant advantage on the electrochemical approach.

# High-performance Liquid Chromatography with Electrochemical Detection for Determining a Ratio of Eicosapentaenoic Acid to Arachidonic Acid in Human Plasma

Akira Kotani, Mizuki Watanabe, Kazuhiro Yamamoto, Fumiyo Kusu, Hideki Hakamata  
School of Pharmacy, Tokyo University of Pharmacy and Life Sciences  
1432-1 Horinouchi, Hachioji, Tokyo 192-0392 JAPAN  
kotani@toyaku.ac.jp

Eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), classified in  $\omega$ -3 polyunsaturated fatty acids (PUFAs), are essential for growth and development, and play an important role in the prevention and treatment of inflammatory and cardiovascular diseases. Recently, it is reported that a ratio of EPA to arachidonic acid (AA) in plasma can be a biomarker for cardiovascular events in a general clinical practice. Gas chromatography with mass spectrometry (GC-MS) and high-performance liquid chromatography with fluorescent detection (HPLC-FL) are applied to determine plasma PUFAs, however, in these methods, the cleanup and derivatization procedures are essential to perform sensitive and selective determination of PUFAs in a real sample analysis. Thus, using simpler sample preparation procedures, a sensitive and selective analytical method for determining PUFAs without derivatization is highly desirable from a practical viewpoint. We had developed a voltammetric method using 3,5-di-*tert*-butyl-1,2-benzoquinone (DBBQ) for determining plasma free fatty acids, showing to be quite sensitive and selective for the acid determination without derivatization of acids. In the present study, an HPLC with electrochemical detection (HPLC-ECD) system was fabricated to determine PUFAs in human plasma. Moreover, the present HPLC-ECD was applied to determine a ratio of EPA to AA in human subject.

The HPLC-ECD was comprised of a degasser, two pumps, a manual sample injector, a column (Develosil C<sub>30</sub>-XG-3, 3  $\mu$ m), an electrochemical detector, and a recorder. An acetonitrile-water mixture (80:20) and that containing 2.0 mmol/L DBBQ and 20 mmol/L lithium perchlorate served as the mobile phase and the DBBQ solution, respectively. The mobile phase and DBBQ solution were made to flow at the rates of 0.03 mL/min and 0.1 mL/min, respectively. A healthy adult male subject was studied upon receipt of his informed consent. The protocol and the subject's informed consent were approved by the Institutional Human Research Committee of Tokyo University of Pharmacy and Life Sciences before commencement of the trial. The blood of 0.1 mL was collected by a finger pricked with a lancing device, and then heparinized blood was separated by centrifugation to obtain plasma. Forty microliter of plasma with nonanoic acid (internal standard) was mixed with 0.4-mL diethyl ether, and PUFAs in plasma were extracted into the diethyl ether phase. The collected diethyl ether was dried completely by nitrogen stream to obtain the lipid residue, which was then dissolved in a 40- $\mu$ L acetonitrile-water mixture (80:20) to prepare a test solution. A 5  $\mu$ L aliquot of test solution was injected into the C<sub>30</sub> column maintained at 30°C, and the eluate was allowed to merge with the DBBQ solution stream to mix together in a mixing tube, and then each PUFA was detected at -0.2 V vs. Ag/AgCl in the electrochemical detector.

The chromatographic peaks of EPA, DHA, nonanoic acid, and AA were observed within 35 min, and these peak heights were found to be proportional to each PUFA concentration, ranging from 0.75  $\mu$ mol/L to 0.1 mmol/L ( $r > 0.998$ ) in all cases. The detection limit of the concentration of each PUFA was 0.23  $\mu$ mol/L. Standard solution of each PUFA at 50  $\mu$ mol/L was determined six times with relative standard deviation (RSD) of less than 3.3%. To estimate an accuracy and precision in the present HPLC-ECD, determinations of PUFAs in human control serum were carried out. The concentration of EPA, DHA, and AA was 10.4, 16.4, and 129  $\mu$ mol/L, respectively, and the repeatability was less than 3.3% RSD. The recovery rate ( $n = 6$ ) of the PUFA for the spiked human control serum in all cases was more than 99.2% and its RSD was less than 5.5%. These results show that the HPLC-ECD method is characterized by higher reproducibility, indicating that the present HPLC-ECD method provides accurate measurements of PUFAs in human serum and plasma. Blood specimen was collected from a healthy human subject subsequent to a fasting for 11 hr, and determination of PUFAs in the human plasma was performed. The concentrations of EPA, DHA, and AA were 4.4, 17.4, and 30.3  $\mu$ mol/L, respectively, thus the ratio of EPA to AA in the human subject was 0.15.

In conclusion, the present HPLC-ECD would be a powerful analytical method for determining ratio of EPA to AA in plasma because it is able to detect PUFAs without the derivatization of acids and the procedure for the sample preparation using a small blood sample would be facile.

# eL-Chem Viewer: A Freeware Package for the Analysis of Electrochemical Data

In electrochemical sensing, a number of voltammetric or amperometric curves are obtained which are subsequently processed, typically by evaluating peak currents and peak potentials or wave heights and half-wave potentials, frequently after background correction. Transformations of voltammetric data can help to extract specific information, e.g., the number of transferred electrons, and can reveal aspects of the studied electrochemical system, e.g., the contribution of adsorption phenomena. In this contribution, we introduce a LabView-based software package, 'eL-Chem Viewer', which is for the analysis of voltammetric and amperometric data, and enables their post-acquisition processing using semiderivative, semiintegral, derivative, integral and elimination procedures. The software supports the single-click transfer of peak/wave current and potential data to spreadsheet software, a feature that greatly improves productivity when constructing calibration curves, trumpet plots and performing similar tasks. eL-Chem Viewer is freeware and can be downloaded from **[www.lchem.cz/elchemviewer.htm](http://www.lchem.cz/elchemviewer.htm)**.

# Square-Wave Adsorptive Stripping Voltammetric Determination of Resveratrol Using Boron-Doped Diamond Electrode in the Presence of Hexadecyl Trimethyl Ammonium Bromide

Yavuz Yardım

*Yüzüncü Yıl University, Faculty of Pharmacy, Department of Analytical Chemistry, 65080 Van,  
Yavuzyardim2002@yahoo.com*

Resveratrol (3,4',5-Trihydroxy-*trans*-stilbene), is a stilbenoid, a type of natural phenol, and a phytoalexin produced naturally by several plants in response to injury or when the plant is under attack by pathogens such as bacteria or fungi . As phenolic compound, resveratrol contributes to the antioxidant potential of red wine and thereby may play a role in the prevention of human cardiovascular diseases. Resveratrol has been shown to modulate the metabolism of lipids, and to inhibit the oxidation of low-density lipoproteins and the aggregation of platelets. Moreover, as phytoestrogen, resveratrol may provide cardiovascular protection. This compound also possesses anti-inflammatory and anticancer properties [1].

In the present paper, a sensitive electroanalytical methodology for the determination of resveratrol using adsorptive stripping voltammetry at a boron-doped diamond (BDD) electrode is presented. In cyclic voltammetry, resveratrol shows one irreversible and adsorption-controlled oxidation peak on BDD electrode. The voltammetric results indicate that in the presence of sodium Hexadecyl trimethyl ammonium bromide (CTAB) the BDD electrode remarkably enhances the oxidation of resveratrol which leads to improvement of peak current with shift of peak potential to less positive values. Using square-wave stripping mode, the compound yielded a well-defined voltammetric response in 0.1 M HNO<sub>3</sub> solution, containing 100  $\mu$ M CTAB at +0.74 V (vs. Ag/AgCl) (after 60 s accumulation at open-circuit condition). Two linear calibration graphs were obtained in the concentration range of 0.025 to 1.0  $\mu$ g mL<sup>-1</sup> ( $1.09 \cdot 10^{-7}$ - $4.38 \cdot 10^{-6}$  M) and 2.5 to 60 ( $1.09 \cdot 10^{-5}$ - $2.63 \cdot 10^{-4}$  M). A detection limit of 0.0063  $\mu$ g mL<sup>-1</sup> ( $2.76 \cdot 10^{-8}$  M), and relative standard deviation of 2.39% for a concentration level of 2.5  $\mu$ g mL<sup>-1</sup> (n = 8) were calculated. As an example, the practical applicability of BDD electrode was tested with the measurement of resveratrol in the dietary supplement products.

E-mail: yavuzyardim2000@yahoo.com

Paracetamol (PAR) / aspirin (ASA) / caffeine (CAF) is a combination drug for the treatment of pain, especially tension headache and migraine. However, an overdose of these mixing drugs may induce nausea, seizures, diarrhea, abdominal pain, vomiting, sweating, confusion or an irregular heartbeat. Thus, their determination in trace quantities is of great importance.

In this study, the electrochemical behaviors of PAR, ASA and CAF on a graphene-nafion (GR-NF) nanocomposite modified glassy carbon electrode (GCE) were investigated by cyclic voltammetry (CV), and adsorptive stripping square-wave voltammetry (AdSSWV).

When a comparative study was carried out employing AdSSWV for PAR, ASA and CAF on bare GCE, GR/GCE and GR-NF/GCE, it could be observed that the best results for both peak current and peak potential were obtained from the GR-NF/GCE (Figure 1). The oxidation peak currents of the three compounds on this electrode were linearly dependent on PAR, ASA and CAF concentrations in the ranges of 0.00125–0.25  $\mu\text{g mL}^{-1}$ , 0.05–5  $\mu\text{g mL}^{-1}$  and 0.05–10  $\mu\text{g mL}^{-1}$  in the individual detection of each component, respectively. By simultaneously changing the concentrations of PAR, ASA and CAF, their electrochemical oxidation peaks appeared at 0.66, 1.04 and 1.45 V, and good linear current responses were obtained in the concentration ranges of 0.00125–0.075  $\mu\text{g mL}^{-1}$ , 0.15–3  $\mu\text{g mL}^{-1}$  and 0.05–2  $\mu\text{g mL}^{-1}$  with the detection limits of 0.00014, 0.0074 and 0.0064  $\mu\text{g mL}^{-1}$ , respectively. The proposed electrochemical sensor was successfully applied for quantifying PAR, ASA and CAF in commercial pharmaceutical formulations without any sample pretreatment. The prepared modified electrode showed several advantages, such as a simple preparation method, high sensitivity, very low detection limits and excellent reproducibility.

**Figure 1.** SW stripping voltammograms of PAR, ASA and CAF (from left to right) in phosphate buffer (pH 2.5) at GCE (red line), GR/GCE (purple line) and GR-NF/GCE (blue line).  $t_{\text{acc}}=60\text{s}$  at open circuit condition; SWV parameters: frequency, 50 Hz; scan increment, 8 mV; pulse amplitude, 30 mV.

# Cocoon Silk-Derived Carbon Nanospheres: Highly Activated Metal-Free Electrocatalysts for Reduction of Dissolved Oxygen and Glucose Sensing

Tongtong Li, Yanyan Song\*

*Research Center for Analytical Sciences, College of Sciences, Northeastern University  
Wenhua Road 3-11, Shenyang 110004, China  
yysong@mail.neu.edu.cn*

In this work, we reported an N-doped porous carbon fiber by calcination of cocoon silk, which is world-widely abundant and has high nitrogen content. Using a simple nitric acid activation of the porous carbon fibers, the carbon nanospheres (CNS) with a diameter of 20-60 nm were achieved. Due to their abundant oxygen-rich groups and nitrogen content, the obtained CNS exhibited excellent electrocatalytic activity and long-term stability towards the reduction of dissolved oxygen at a low operating potential. The modified electrode based on CNS film displayed a linear range from 5.1 to 64.8  $\mu\text{M}$  and detection limit of 0.15  $\mu\text{M}$ . Considering the excellent electrocatalytic activity of the CNS toward the reduction of oxygen, the CNS were further applied in the construction of glucose amperometric biosensor using glucose oxidase as a model. The proposed glucose biosensor showed fast response (within 4 s), good stability and satisfied selectivity for glucose detection with a wide linear range from 79.7 to 2038.9  $\mu\text{M}$ , and a detection limit of 39.1  $\mu\text{M}$ . This work demonstrates the feasibility of CNS modified electrode in sensing application, and provides an effective approach to prepare CNS-based amperometric biosensors.

## Detection of semivolatile organic compounds (VOCs) in wastewater through current output of electrochemically active bacteria

Abeed Fatima Binti Mohidin Batcha, Kannan Palanisamy, Carlo Sntoro, Maria Yung, Thomas Seviour, Jamie Hinks, Federico Lauro and Enrico Marsili  
Singapore Centre on Environmental Life Sciences Engineering, Nanyang Technological University,  
60 Nanyang Drive, 637551 Singapore  
emarsili@ntu.edu.sg

Volatile and semi-volatile organic compounds (VOCs) are pollutants of concern, because they can be toxic to both microorganisms and humans. While some VOCs like N-methyl-2-pyrrolidone or dibutyl phthalate can be easily degraded in sludge and sewage water [1] or in the soil [2], other like 2,5-pyrrolidinedione, 1-methyl are poorly characterized in terms of their toxicity and environmental impacts. Semi-volatile VOCs are common organic solvents and are found in wastewater from electronics and textile industry. At concentration as low as 10-100 mg L<sup>-1</sup>, VOCs contribute to failure of used water treatment processes either through direct inhibition of biomass or because they are not degraded during biological treatment and are discharged in the effluent. Environmental, low cost detection of VOC is highly desirable in Singapore, because of its widely spread sewage network. Current methods for VOC detection are costly and often require off-line analysis. These shortcomings make current technology incompatible with distributed environmental VOC sensing.

Bioelectrochemical systems (BESs) represent an emerging technology that exploits so-called electroactive bacteria (EABs) to catalyze redox reactions at solid electrodes. The anodic current produced in BESs depends on the fitness of viable EABs in the device. Therefore, BESs can be used to sense toxic chemicals, as the latter decrease the vitality of the EAB community in the anodic chamber and hence current output. EABs capable of electron transfer to solid state electrodes are commonly encountered in used water and a BES that maintain a constant current output can be deployed with minimum material cost. In this study, we adopted screen printed graphite electrode coated with carbon nanotubes. EABs grown on these high surface electrodes produce high and stable current after few hours from inoculation.

We present results for amperometric detection of selected VOC in *Pseudomonas aeruginosa* and *Escherichia coli* pure cultures. Exogenous redox mediators (e.g., riboflavin, pyocyanin, AQDS and HNQ) were added to increase the current output and therefore the sensitivity to VOCs. Chronoamperometry was performed at oxidative potential (0.2 V vs. Ag/AgCl) on screen printed graphite electrodes coated with carbon nanotubes. In this setup, VOC detection limit was <25 ppm and response time was <1 min. The linear response range was 0-300 ppm for most of the VOC investigated. While the specificity of the proposed sensor requires further investigation (ongoing), this represent the first step for the development of genetically engineered community capable of high sensitivity and high selectivity VOC detection.

netaoaquino@yahoo.com.br

Among the various alternative technologies for efficient energy conversion that have been developed over the past few decades, the use of enzymes immobilized onto the surface of electrodes as the main catalyst in biological fuel cells has been extensively reported. In this work, we explore the bioelectrooxidation of ethanol using PQQ-dependent alcohol and aldehyde dehydrogenase (ADH and AldDH) enzymes for biofuel cell applications. The bioanode architectures were designed in both direct electron transfer (DET) and mediated electron transfer (MET) mechanisms employing high surface area materials such as multi-walled carbon nanotubes (MWCNTs) and MWCNT-decorated gold nanoparticles along with different immobilization techniques. From the different polymeric matrices tested (tetrabutyl ammonium bromide (TBAB)-modified Nafion; octyl-modified linear polyethyleneimine (C8-LPEI); and cellulose) in DET studies, the modified Nafion membrane provided the best electrical communication between enzymes and the electrode surface, with catalytic currents as high as  $16.8 \pm 2.1 \mu\text{A cm}^{-2}$ . Considering the MET studies, the redox polymer 1,1'-dimethylferrocene-modified linear polyethyleneimine (FcMe<sub>2</sub>-C<sub>3</sub>-LPEI) provided the best electrochemical response. Using this polymer, the electrochemical assays conducted in the presence of MWCNTs and MWCNTs-Au indicated a  $J_{\text{max}}$  of  $781 \pm 59 \mu\text{A cm}^{-2}$  and  $925 \pm 68 \mu\text{A cm}^{-2}$ , respectively. Overall, from the results here obtained, DET using the PQQ-dependent ADH and AldDH still lacks of high current density generated, while the bioanodes that operate via MET employing Fc-modified LPEI redox polymers show efficient energy conversion capability.

Figure 1. Representative cyclic voltammograms of the bioanodes based on FcMe<sub>2</sub>-C<sub>3</sub>-LPEI prepared with MWCNTs or MWCNTs-Au in the absence and in the presence of 20 mM ethanol (left) and power density curves obtained in ethanol/O<sub>2</sub> biofuel cell tests (right).

# Luminol Electrochemical-luminescence for Single Cell Analysis

Dechen Jiang

*School of Chemistry and Chemical Engineering, Nanjing University  
22 Hankou Rd, Nanjing, Jiangsu, 210092  
dechenjiang@nju.edu.cn*

Electrochemical imaging of single living cells suffers limitations owing to low throughput associated with scanning electrochemical microscopy, and to undesirably high detection limit associated with surface-plasmon-resonance-based electrochemical imaging techniques. In our group, luminol electrochemiluminescence (ECL) was applied for the imaging of hydrogen peroxide in single living cells with a spatial resolution of 0.8  $\mu\text{m}$ , thus establishing a novel electrochemical imaging technique for single cells with high analysis throughput and low detection limit. The technique was expanded to image surface-confined molecules by coupling the reaction of the molecules with their corresponding oxidase to generate hydrogen peroxide. Using this strategy, active membrane cholesterol was imaged in single cells, which could not be achieved using fluorescent assay. Compared with fluorescence assay that needed design the specific probe for each molecule, our ECL imaging strategy was universal for more molecules with the aid of commercial oxidases, and can distinguish the molecules with different chemical activity at cells. This success in ECL imaging of single living cells opens a new field in the imaging of biological samples.

# DNA Heptamers with Different Central Trinucleotide Sequences Studied by Electrochemical and Spectral Methods

Iveta Pilarova <sup>a</sup>, Libuse Trnkova <sup>a,b</sup>

<sup>a</sup>*Department of Chemistry, Faculty of Science, Masaryk University, Kamenice 5, Brno 625 00, Czech Republic*

<sup>b</sup>*Central European Institute of Technology, Brno, University of Technology, Technicka 3058/10, 616 00 Brno, Czech Republic e-mail: [libuse@chemi.muni.cz](mailto:libuse@chemi.muni.cz)*

Monitoring the relationship between a structure and the corresponding electrochemical response is very important not only from the aspect of the knowledge of dynamic structural changes to the charged interface (electrode surface, membrane, surface of the gel), but also in terms of proper evaluation of the electrochemical signals for potential biosensors. This relationship was studied for the case of short DNA fragments, the heptamer d(GCGAAGC) with its analogs carrying different trinucleotide sequences in the center of the molecule (XXX = AAA, CCC, GGG or TTT) and hexamers of d(GCGAGC) type with different dinucleotide sequences. All fragments were investigated by spectral methods (CD and UV spectra) and electrochemical methods (cyclic and linear sweep voltammetry, polyacrylamide gel electrophoresis). For deeper understanding of DNA heptamers and hexamers behavior on the electrode surface (mercury and carbon) the elimination voltammetric procedure (EVP) for reduction and oxidation responses was used. The EVP indicated strong adsorption of reduced form of guanine on a mercury electrode (readable peak-counterpeak signal). Our results showed that (i) the central triplet GAA or AAA dramatically stabilizes DNA heptamers, (ii) a stem-loop configuration is not supported by CCC or TTT sequences, instead, these heptamers adopt bimolecular duplex forms, and finally (iii) in the case of GGG sequence a very stable supramolecular G - quadruplex is formed. In the next experiments, we compared DNA and RNA fragments. DNA heptamers and hexamers provided double oxidation peaks (GI and GII) while RNA analogs provide only a single G peak. Based on this fact, DNA or RNA fragments can be quickly and inexpensively distinguished.

# Nitrogen-doped Carbon Electrodes for Simultaneous Detection of Dopamine, Uric Acid and Ascorbic Acid

Ming-Chang Yang, Yi-Kai Chih, and Ya-Yun Zhan

Department of Chemical Engineering, National Cheng Kung University

University Rd. 1, East District, Tainan, Taiwan 70101

mcyang@mail.ncku.edu.tw

Dopamine (DA), uric acid (UA) and ascorbic acid (AA) are important biomolecules in human bodies. Previous studies have proven that many diseases are associated with their concentrations. Abnormal secretion of DA can lead to schizophrenia and Parkinson's disease. High concentrations of UA can lead to hyperuricemia, gout, and other diseases. AA is a powerful antioxidant that is effective against the superoxide radical, the hydroxyl radical. The content of AA in biological fluids can be prevented cancer, diabetes and hepatic disease. Monitoring the concentrations of DA, UA and AA in blood or urine is an effective early warning sign for central nervous system or kidney diseases.

Two nitrogen-doped carbon materials were successfully applied to detect DA, UA and AA simultaneously in this report. For the first material, graphene oxide (GO) was synthesized from graphite powder by a modified Hummers method. Polyvinylpyrrolidone (PVP) was then mixed with GO dispersion in water. After heat treatment in oven, the thermally reduced GO was doped with nitrogen (NGO). The carbon material is coated on glassy carbon electrode with binder of Nafion. The differential pulse voltammogram (DPV) showed the detection peaks for DA, UA and AA are well separated (fig. 1). The heat treatment condition played important effect on the detection ability. Other effects of the preparation condition on the sensing behaviors will be reported.

Fig. 1 DPVs for GCE/r-NGO-Nafion electrode and other electrodes in 0.1M PBS (pH 7.0) containing 10  $\mu$ M DA, 180  $\mu$ M UA and 1,000  $\mu$ M AA.

For the second material, dopamine was first polymerized on zinc oxide nanoparticles. After pyrolysis in nitrogen atmosphere, mesoporous carbon material formed with nitrogen doping. Hollow-type mesoporous carbon with nitrogen doping formed after template removal. The carbon material was coating on electrode and showed good peak separation for DA, UA and AA (fig. 2). The amount of ink for coating affected the sensing ability. Other effects of the preparation conditions on the sensing behaviors will be also reported.

Fig. 2 DPVs for nitrogen-doped hollow mesoporous carbon in 0.1M PBS (pH 7.0) containing 10  $\mu$ M DA, 90  $\mu$ M UA and 500  $\mu$ M AA.

# Surface-Enhanced Raman Spectroscopic study of a DNA Beacon Probe Immobilized at a Au Electrode

<sup>1</sup>Chemistry, University of Southampton, Southampton, SO17 1BJ, UK.

<sup>2</sup>Department of Chemistry, University of Oxford, Chemistry Research Laboratory, 112 Mansfield Road, Oxford, OX1 3TA, UK.

yl46g11@soton.ac.uk

The conformational changes of oligonucleotides at charged surfaces are a core issue in the development of biosensors<sup>1-3</sup>. In the present work we used a 35 mer beacon probe having a 7 mer self-complementary region at both termini. The beacon probe was labeled with Texas Red at the 3' end as a Raman label and attached to the gold surface through three cyclic disulfides at the 5' end together with mercaptohexanol to passivate the surface. Electrochemical and Raman measurements were made simultaneously on sphere segment void (SSV)<sup>4</sup> SERS active surfaces. On scanning the potential two overlapping potential regions show distinct reversibility in the SER spectra. On the first cathodic cycle the mercaptohexanol reductively desorbs [2] around -0.7 V leading to a restructuring of the immobilised oligonucleotide which is seen in the SER spectra which then stabilise on repeated cycling. Over the potential region from -0.3 to -0.9 V vs. Ag/AgCl, the surface structure contained desorbed mercaptohexanol reorganized the packing structure with beacon probe to form a quasi-stable self-assembly monolayer on the surface<sup>2</sup>. This observation provides insight into the behavior of the immobilized DNA on a mercaptohexanol-passivated electrode that is of benefit to DNA biosensor working at negative potentials.

Mis en forme : Non Surlignage

**Figure.** Five consecutive scans from -0.3 to -0.9 V vs. Ag/AgCl and back recorded at 1 mV/s for a DNA beacon probe immobilized at a gold SSV surface together with mercaptohexanol. a) The voltammetric response (only the first two scans are shown for clarity; b) the corresponding variation in the intensity of Texas Red band in the SER spectrum at  $1500 \text{ cm}^{-1}$ .

Nitrite in physiological systems can form nitrosamines by interacting with amines, which are toxic and carcinogenic substances, and thus brings serious problems, such as eutrophications and many potential hazards to human health [1-2]. Therefore, accurate determination of nitrite is important to reduce human health risks. Many techniques have been developed for determining nitrite, such as flow injection analysis, colorimetric method, chemiluminescence, and electrochemical analysis. Recently, metal-organic frameworks (MOF), [3] a class of three-dimensional (3D) porous materials constructed of organic linkers and metal-based nodes, have shown their great potential in electrochemical applications due to their ultrahigh surface area, regular nanostructured pores, and high permanent porosity.

In this study, we fabricate a thin film MOF sensor for nitrite based on inkjet printing technology. First, specific MOF-525 nanocubes with high electrocatalytic activity toward nitrite oxidation is synthesized and categorized by size. With proper ink formulation and particle suspension, MOF-525 inks are inkjet-printed to form uniform thin films on gold electrodes to find the optimal size for nitrite sensing. The sensitivity, stability and repeatability with potential applications of the printed sensors will be carefully examined to demonstrate the feasibility of printed sensors for quick and accurate determination of nitrite.

# Anthraquinone labelled DNA for direct detection and discrimination of closely related DNA targets

Rachel Gao<sup>a</sup>, Sarah A. Goodchild<sup>b</sup> and Phillip N. Bartlett<sup>a</sup>

<sup>a</sup>*School of Chemistry, University of Southampton, Southampton, SO17 1BJ*

<sup>b</sup>*DSTL, Porton Down, Salisbury, Wiltshire, SP4 0JQ*

*rg805@soton.ac.uk*

A novel detection approach using immobilised DNA probes labelled with Anthraquinone (AQ) as an electrochemically active reporter moiety has been successfully developed as a new, simple, reliable method for the detection of DNA. This method represents a step forward in DNA detection as it can discriminate between multiple nucleotide polymorphisms within target DNA strands without the need for any additional reagents, reporters or processes such as melting of DNA strands. The detection approach utilises single stranded DNA probes immobilised on gold surfaces labelled at the distal terminus with AQ. The effective immobilisation has been monitored using techniques such as AC impedance and Raman spectroscopy. Simple voltammetry techniques (Differential Pulse Voltammetry, Cyclic Voltammetry) are then used to monitor the reduction potential of the AQ before and after the addition of complementary strand of target DNA. A reliable relationship between the shift in reduction potential and the number of base pair mismatch has been established and can be used to discriminate between DNA from highly related pathogenic organisms of clinical importance. This indicates that this approach may have great potential to be exploited within biosensor kits for detection and diagnosis of pathogenic organisms in Point of Care devices.

Lo.Gorton@biochemistry.lu.se

Electrochemical transfer communication between bacterial cells/biological membranes and electrodes can usually be obtained through the use of freely diffusing monomeric redox mediators. Previously we have, however, also shown that flexible osmium redox polymers can work as efficient mediators for a number of both Gram– as well as Gram+ bacteria and electrodes, clearly showing that the mediator does not need to pass the inner membrane to be able to shuttle the charge between the cells and the electrode [1,2]. As a continuation of our work on bacterial cells [3-8] we have now turned to various photosynthetic organisms/membrane systems. Here we report on electrochemical communication between whole viable photosynthetic bacterial cells (*Rhodobacter capsulatus* [9,10] and *Leptolyngbia* sp. [11].) as well as with eukaryote systems (thylakoid membranes from spinach [12,13], the eukaryote unicellular algae *Paulschulzia pseudovolvox* [14]) and electrodes through the use of osmium redox polymers. Here we also report on how to increase the efficiency of the charge transfer from the photosynthetic reaction centres to the electrode as well as to increase the stability of the system.

Microbial fuel cell system (MFCs) is a source technique for bio-electrochemical system (BES) including biosensors, bio-energy system, and especially bioelectronics device such as microbial electrolysis cell, microbial electro-synthesis cell, and microbial desalination cell and so on [1]. The MFCs is a device that produce bio-electricity by converting chemical energy to generate electricity with microbial metabolism [2]. Thus, the MFCs is also belongs to one part of the fuel cell. The biggest difference between the MFC and the typical fuel cell is the use of living organisms which is electrogenic bacteria as anodic catalysis to produce electron on anode [3]. For this reason, the advantage of the MFCs is use of a wide range of environment-friendly energy source, e.g., organic/inorganic compound in lake water, muds, wastewater, and sludge etc. On the other hand, a current production aspect is extremely low compared to the typical proton exchange membrane fuel cell (PEMFC) due to low anodic kinetic activity of the living organism. In addition, the working voltage of MFCs is also not enough that is around 0.2 ~ 0.5 V. Hence, to commercialize the MFCs, increases of currents as well as voltages are necessary [4]. To meet the needs, stack system has been frequently tried in MFCs with power management system. However, when the MFCs are connected as serially, a voltage reversal is seriously occurred which is the voltage of unit cell connected in series is reversed [5]. In this situation, the reversed unit cell is not working as galvanic cell, and it is working as electrolysis cell. In the PEMFC, the voltage reversal is generated mainly by fuel starvation and fuel crossover. However, in the MFCs, the voltage reversal is mainly occurred by unbalance of unit cells' performances, especially kinetic difference of unit cells. The voltage reversal is more magnified at scale-up of MFCs for commercialization. Therefore in this paper, to understand the reason of voltage reversal in MFCs, and also to prevent the voltage reversal, multiple electrode MFC was designed [6] and assistance current method was suggested with controlling current system [7].

# Hydrogenated and 4-Sulfobenzene Modified Conical-tip Carbon Electrodes with Antifouling Property for Sensitive Detection of Dopamine

Shajahan Siraj, Danny K. Y. Wong

*Department of Chemistry and Biomolecular Science, Macquarie University*

*Sydney, NSW 2109, Australia*

*shajahan.siraj@students.mq.edu.au*

In this work, we report the development and application of physically small conical-tip carbon electrodes (approximately 2  $\mu\text{m}$  diameter and 15  $\mu\text{m}$  axial length), consisting of a hydrophobic surface that was grafted with a 4-sulfobenzene layer, as an antifouling sensor to the detection of the neurotransmitter dopamine. During detection of dopamine *in vivo*, amphiphilic proteins, peptides and lipids present in extracellular fluid can easily adsorb on an electrode surface and cause fouling. This surface barrier prevents dopamine from making contact with the electrode for electron transfer reaction, yielding a slowly diminishing transient detection signal. This may then give rise to results that are less meaningful. In our work, we exploit a hydrophobic carbon surface, achieved by hydrogenating the carbon electrode using an *n*-butylsilane reduction method, to discourage adsorption of the amphiphilic species. In addition, a bonus is that the hydrophobic surface was found to be unfavourable for the oxidation of ascorbic acid, which is often a major interfering agent during dopamine detection. However, after hydrogenation, slower dopamine oxidation kinetics were observed at these modified electrodes, resulting in a 13% decrease of the dopamine oxidation current. This is also supported by an increase in the charge transfer resistance of dopamine at the hydrophobic electrode compared to that at a bare electrode, as determined by electrochemical impedance spectroscopy. Next, a 4-sulfobenzene layer was immobilised on the electrode to introduce negatively charged groups for electrostatic attraction towards positively charged dopamine (under physiological pH) and thus increase the electron transfer kinetics of dopamine at the electrode. In characterising the modified electrodes, we observed a 4% increase in the reduction current of  $[\text{Ru}(\text{NH}_3)_6]^{3+}$  and a 4% increase in the oxidation current of dopamine owing to enhanced adsorption of the analytes on the grafted sulfobenzene layer. More significantly, the fabricated electrodes retained 87% sensitivity to dopamine after being incubated in a synthetic fouling solution containing 1.0% (v/v) caproic acid (a lipid), 4% (w/v) bovine serum albumin and 0.01% (w/v) cytochrome c (both are proteins), and 0.002% (w/v) human fibrinopeptide B (a peptide) for 30 min. In contrast, hydrogenated electrodes were found to retain only 65% sensitivity in dopamine detection under identical experimental conditions. These results support minimal fouling at the fabricated electrodes *in vitro*.

# Probing Laccase Immobilization on Modified Gold Electrodes and Conformational Changes by Surface-Enhanced Infrared Absorption Spectroscopy

Maciej Karaskiewicz, Jerzy Rogalski, Renata Bilewicz, Jacek Lipkowski

mkaraskiewicz@chem.uw.edu.pl

Reduction of oxygen catalysed by blue-copper oxidases (e.g. laccase) is a common reaction applied in biofuel cells [1]. Therefore, better understanding of enzyme electrode reaction and orientation of laccase on the electrode may have great impact on the efficiency of oxygen reduction and, as a result, on the biofuel cell characteristics. There are several techniques suitable for in-depth studies of structural changes of enzymes *in-situ*. One of them is surface-enhanced infrared absorption spectroscopy (SEIRAS) combined with the electrochemical techniques. They allow to probe adsorption and conformational changes at various potentials [2]. In our work, laccase molecules were adsorbed on modified carbon nanotubes (CNTs). SEIRAS spectra of laccase adsorbed on CNTs recorded in the presence and absence of oxygen show sharp changes in intensity of Amide I and Amide II bands depending on potential, suggesting strong structural changes of  $\alpha$ -helix and minor  $\beta$ -sheet region of laccase molecule. It has been shown that gold electrodes covered with modified carbon nanotubes have completely different properties for the immobilization of enzymes compared to the SAM systems reported elsewhere [3]. It has been proven that a favorable environment for the immobilization of enzymes are carbon nanotubes and the amide I band of such a system occurs at a wavenumber, characteristic for the main, secondary and tertiary structure of laccase  $\beta$ -sheet. Synchronous spectra obtained by two-dimensional correlation spectroscopy, in argon and oxygen saturated solutions, show that laccase conformational changes take place mainly in the vicinity of active sites, which is the area of the  $\alpha$ -helix.

Fig. Scheme of described SEIRA system and thin film of gold modified with CNTs and laccase.

# Bioelectrocatalysis with sol-gel biocomposite layers deposited onto porous electrodes

Alain WALCARIUS

*Laboratoire de Chimie Physique et Microbiologie pour l'Environnement (LCPME)  
UMR 7564 CNRS – Université de Lorraine, 405, rue de Vandoeuvre, 54600 Villers-les-Nancy, France  
alain.walcarius@univ-lorraine.fr*

Sol-gel-derived silica-based materials offer attractive features (rigid three-dimensional framework ensuring fast mass transport, ease of modification with a variety of organo-functional groups, host for various reactants, including biomolecules), which can be advantageously exploited in electrochemistry, at the condition to be manufactured in a controlled way ensuring a close contact to an electrode surface (e.g., as thin films of uniform morphology and homogeneous composition). Sol-gel thin films on electrodes are usually prepared by dip- or spin-coating, for which film formation occurs via solvent evaporation and concomitant condensation of the precursors. The approach operates quite well but it is basically restricted to deposition onto flat surfaces only (it may suffer from some drawbacks when applied to the modification of high surface area porous electrodes, such as pore blocking). On the other hand, sol-gel matrices are attractive hosts for enzymes owing to their excellent biocompatibility and thanks to the soft conditions associated to sol-gel processing. On that basis, significant developments appeared in the past on the use of sol-gel materials for elaborating electrochemical biosensors [1].

It will be discussed here how the electrochemically-assisted generation of bio-doped sol-gel films on highly porous electrodes with large surface areas constitutes an attractive method for bioelectrocatalysis purposes, notably for applications as electrochemical bioreactors for the production of fine chemicals. This will be exemplified here on the basis of dehydrogenase-type enzymes.

Functionalized silica thin films can be generated via an electrochemically-driven deposition method implying a local electrochemical tuning of pH at the electrode/solution interface to induce precursor condensation in a controlled way [2,3]. This approach is compatible with biomolecule encapsulation while maintaining its biological activity [4,5]. It can be applied to uniform deposition onto nanostructured electrodes such as macroporous gold [4] or assemblies of electrospun platinum fibers [5]. This strategy has been applied for the design of bioelectrocatalytic reactors made of dehydrogenase-based sol-gel films deposited over large area porous electrodes [6-9]. They were also molecularly engineered in the same time to include the co-factors and mediators necessary to build reagent-free electrochemical bioreactors [7-9]. Once again, electrochemistry was particularly attractive as it constitutes a unique way to deposit such biohybrids as uniform thin films onto non-flat surfaces of complex geometry (e.g., carbon felt electrodes, nanotubes assemblies, ordered macroporous electrodes), which are essential to get reactors with high yields and good operational stability [10].

# Biocathode based on a MgO-template Carbon Electrode Modified with ABTS and Bilirubin Oxidase

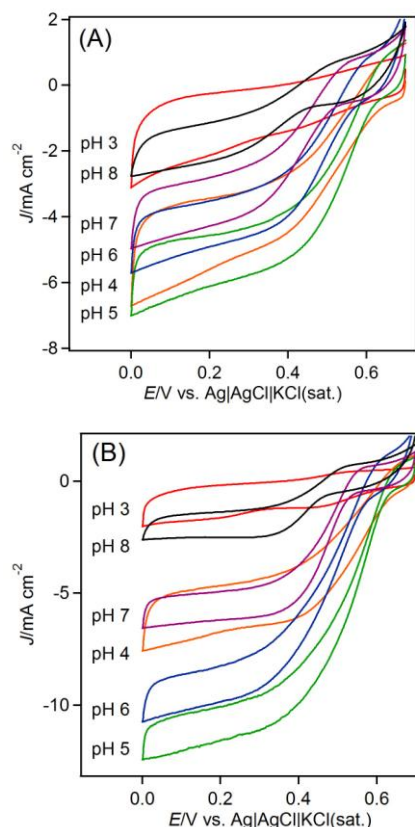

Seiya Tsujimura, Kazuki Murata

Division of Materials Science, Faculty of Pure and Applied Sciences, University of Tsukuba

1-1-1 Tennodai, Tsukuba, Ibaraki 305-8573, Japan

seiya@ims.tsukuba.ac.jp

Bilirubin oxidase (BOD) from *Myrothecium verrucaria* is one of the most widely used bioelectrocatalysts for the four-electron oxygen reduction reaction (ORR) under neutral pH conditions [1]. The interfacial electron transfer rate depends on the electron transfer distance between the electrode surface and the enzyme electrochemically active site, and the magnitude of the maximum catalytic current depends on the effective surface area available for the electrochemical reaction involving BOD. Therefore, when a mesoporous carbon electrode such as MgO-templated carbon (MgOC) [2] is used, BOD showed as high catalytic current density as 6 mA per geometric surface area, without a mediator on the rotating disk voltammetry at pH 5, 8000 rpm (Figure 1(A)). In order to improve the cathode performance, surface modifications were also exploited to enhance interfacial electron transfer from the electrode surface to the active site of BOD, or by loading BOD onto the surface by providing suitable attractive interactions. For example, enhanced catalytic current and stability of the BOD were reported on the electrode modified with 6-amino-2-naphthoic acid or bilirubin [3,4]. Meanwhile, in this study, by simply applying a solution consisting of a mixture of BOD and 2,2'-Azinobis(3-ethylbenzothiazolin-6-sulfonate) (ABTS) to the porous carbon, both of these compounds can be adsorbed on the electrode surface. The ABTS molecules can be adsorbed on the surface of MgOC and shows very stable redox behavior without undergoing a disproportionation, which would cause the degradation of these molecules. The maximum catalytic current increased twice in the presence of ABTS across a wide pH range (Figure 1(B)). The pH-dependence of the oxygen reduction voltammogram revealed that the ABTS adsorbed on the electrode surface accelerated the direct and mediated electron transfer rates by improving the orientation of BOD on the carbon surface or enhancing enzyme loading favorable for the electron transfer, and by mediating the electron transfer from the electrode to the electro-active site of BOD. We will also present a gas-diffusion type biocathode using MgOC with PTFE as a binder based on BOD/ABTS system.

**Fig. 1.** Rotating cyclic voltammograms for the ORR on BOD-MgOC-E (A) and BOD/ABTS-MgOC-E (B) at pH 3.0, 4.0, 5.0, 6.0, 7.0, and 8.0 under O<sub>2</sub>-saturated conditions at 25 °C at 8000 rpm. Scan rate: 5 mV s<sup>-1</sup>.

# Negative dielectrophoretic separation of cells based on the expression of specific surface antigen

Tomoyuki Yasukawa, Yuki Minakuchi, Hironobu Hatanaka, Fumio Mizutani  
Graduate School of Material Science, University of Hyogo  
3-2-1 Kouto, Kamigori, Ako, Hyogo 678-1297, Japan  
E-mail: yasu@sci.u-hyogo.ac.jp

**Introduction:** The expression patterns of surface antigens on cells are related to various diseases and differentiation. We have been applied dielectrophoresis (DEP) to fabricate the particle and cell pattern and applied particle manipulation for rapid and simple immunosensing. Recently, we also applied the combination of positive DEP (p-DEP) and negative DEP (n-DEP) to capture the specific cells by immunoreactions and separate the cells with specific surface antigen from a cell population. The use of this system enabled the rapid (3 min) and simple (label free) discrimination of specific cells. However, the cell binding efficiency was approximately half due to the use of a cell suspension medium with relatively low conductivity in which immunoreactivity is low. Unfortunately, no living cell experienced the attractive force of p-DEP in the higher conductivity region within the used frequency region (10 kHz–10 MHz). In this presentation, we employed n-DEP to fabricate two different cell patterns by switching the applied voltage and applied the method to discriminate and separate cells with a target antigen with high binding efficiency.

**Experiment methods:** Figure 1 depicts the method for detecting the surface antigen. The suspension of HL-60 cells with CD33 antigen was introduced into the device consisted of an upper indium tin oxide (ITO) electrode and a lower ITO-interdigitated band array (ITO-IDA) electrode. The surface of the ITO-IDA electrode substrate was modified with the anti-CD 33 antibody. When AC voltage is applied between the upper ITO and lower ITO-IDA electrodes, the cells accumulate at the gap regions between the IDA bands by n-DEP, thereby accelerating the capture of cells with the target antigen via an immunoreaction. After the applied voltage for band B was switched off, electric fields disappeared between the upper ITO and band B and appeared between bands A and B, thereby leading to the formation of relatively weak electric field areas above band B. Thus, unbound cells were removed from the gap region to the area above band B to form another line pattern. The ratio of the captured cell density (cell binding efficiency) was calculated from the optical images of the two different patterns.

**Results and discussion:** Cells dispersed randomly in the channel and rapidly accumulated in the gap area between the bands within 5 s due to the repulsive force of n-DEP. We removed the cells accumulated in the gap by switching the voltage of band B to zero 60 s after cells had accumulated. When the cells accumulated in the gap modified with anti-CD33, some cells moved to the area above band B, whereas others remained even after the band B voltage was switched to zero. In contrast, almost all cells moved to the area above band B after voltage was switched to zero, and cells accumulated in the gap modified with non-specific anti-mouse IgG. These results indicate that the cells with CD33 surface antigens reacted with the antibodies to be irreversibly captured at that position. Cell binding efficiency was estimated from the steady-state value and was  $68.3 \pm 3.2\%$ . Moreover, the swing of accumulated cells allowed further improvement of cell binding efficiency ( $83.9 \pm 1.4\%$ ). Times as short as 60 s and 30 s were required to capture the cells with immunoreactions and to remove unbound cells, respectively. Therefore, cells with CD33 cell surface antigens could be rapidly identified from the cell suspension with high binding efficiency by spatial separation based on an immunoreaction and manipulation by n-DEP.

Fig. 1 Discrimination of cells with specific surface antigens using n-DEP manipulation.

# Redox polymers @ bioelectrochemistry. From biosensors to biofuel cells and self-powered bioelectrochemical devices

Wiring of redox enzymes to electrodes surfaces is of key for optimization of properties of biosensors, biofuel cells and bioelectrochemical devices. Besides the adaptation of the formal potential of the polymer bound redox relay to the active site of the polymer-integrated biological recognition element, the properties of the polymer backbone itself, the swelling properties, the permeability for substrate and products, restricting the access of potentially interfering compounds and adding suitable anti-interference layers is of high importance. Moreover, strategies for non-manual immobilization of all components in a highly reproducible way even allowing the formation of complex bioelectrochemically active layers is becoming increasingly important.

In this contribution, we suggest a new strategy for the rational build-up of complex sensor architectures using the previously reported electrochemically induced activation of bifunctional crosslinkers by cleaving off the protecting groups [1]. By careful design of the redox polymers using novel strategies for achieving more uniform molecular-weight distribution together with high loading of the redox relay and crosslinkable sites a new generation of bioelectrodes was achieved. Examples will include the protection

of sensitive enzymes within redox polymers, the design of biofuel cells with high open circuit voltage and high power densities, the use of these type of biofuel cells in self-powered bioelectrochemical devices e.g. for glucose determination or antibiotic determination in milk. The self-powered bioelectrochemical devices were further extended to instrument free bioelectrochemical devices by converting the biocatalytic current into an optical read-out capability.

\*masato@gpo.kumamoto-u.ac.jp

Direct electron transfer (DET) reaction between multicopper oxidases, especially laccase (Lac) and bilirubin oxidase, and a carbon electrode has been widely studied as fuel cell electrode for oxygen reduction in an enzymatic bio-cathode. Great effort has been directed toward studying the design of electrode interface to be given suitable enzyme molecular orientation for the DET reaction. The electrode interface modified with an organic compound such as anthracene has gave the enhanced bioelectrocatalytic current of Lac.<sup>1</sup> Here, we present acceleration of the DET of Lac with the interface of single-walled carbon nanotubes (SWCNTs) modified with steroid-type biosurfactants.<sup>2</sup>

Sodium cholate (SC) and sodium taurocholate (ST) were used as a steroid-type biosurfactant. SWCNTs were synthesized onto a gold surface as described in previous reports.<sup>3</sup> Immediately after synthesis, the fresh SWCNT electrodes were immersed into 0.1 wt% SC or ST aqueous solutions for 24 hrs (Fig. 1). After rinsed gently, the modified SWCNT electrodes were immersed into 0.1 mol dm<sup>-3</sup> acetate buffer solution (pH 5) containing 10 μmol dm<sup>-3</sup> Lac for 30 min. A 1.0 mol dm<sup>-3</sup> phosphate-citrate buffer solution (pH 3.0) was used as an electrolyte solution, and was purged with high-purity argon before taking measurements.

The surface concentrations of the adsorbed Lac at SC-, ST-modified and none-modified SWCNT surfaces were evaluated to be 2.4, 2.3, and 2.2 pmol cm<sup>-2</sup>, respectively, which were less than monolayer level. The onset potentials at which the Lac started to catalyze the electrochemical reduction of O<sub>2</sub> at SC- and ST-SWCNTs, were 0.998 and 0.977 V (vs. NHE) respectively, which were higher than that observed at none-modified SWCNTs (Fig. 2). From the analysis of steady-state current density ( $j_a$ ) using the adsorption model given by  $j_a = nFk_c\Gamma_a / (1 + (k_c/k_f) + (k_b/k_f))$ ,  $k_f = k^\circ \exp[-\alpha(nF/RT)(E^\circ - E^\circ)]$ ,  $k_b = k^\circ \exp[(1-\alpha)(nF/RT)(E^\circ - E^\circ)]$  ( $n=1$ ,  $k_c=2600$  s<sup>-1</sup>,  $E^\circ=0.925$  V,  $T=298.15$ ),<sup>4</sup> the  $k^\circ$  values were determined to be 3000 and 1500 s<sup>-1</sup> at the SC- and ST-SWCNTs, respectively.<sup>2</sup> On the other hand, the  $k^\circ$  value at none-modified SWCNTs was 400 s<sup>-1</sup>.

<sup>a</sup> The 3D structures are optimized.

# Naphthoquinone Derivatives as Low-Potential Electron Mediators of FAD-Dependent Glucose Dehydrogenase

Ross D. Milton<sup>a</sup>, David P. Hickey<sup>a</sup>, Sofiene Abdellaoui<sup>a</sup>, Koun Lim<sup>a</sup>, Boxuan Tan<sup>a</sup> and Shelley D. Minter<sup>a</sup>

<sup>a</sup>Department of Chemistry, University of Utah, 315 S 1400 E Rm 2020, Salt Lake City, Utah, 84112, USA.  
minter@chem.utah.edu

Flavin adenine dinucleotide-dependent glucose dehydrogenase (FAD-GDH) is rapidly emerging as an alternative glucose-oxidizing enzyme for enzymatic fuel cell (EFC) applications.<sup>1, 2</sup> The FAD cofactor has a relatively low redox potential (in comparison to heme-based and PQQ-dependent enzymes). Furthermore, FAD-GDH has the added benefit over its commonly used counterpart, glucose oxidase (GOx), of not undergoing the parasitic reduction of O<sub>2</sub> to H<sub>2</sub>O<sub>2</sub>, which can be troublesome in EFC applications.<sup>3</sup> Unfavorable electron transfer competition at the bioanode and dissolved O<sub>2</sub> depletion (important for most enzymatic O<sub>2</sub>-reducing cathodes) can be avoided.

Recent works have demonstrated how the use of FAD-GDH can be useful in high-power EFC applications. Maximum current densities of 100 mA cm<sup>-2</sup> have been reported with the use of an osmium-based redox hydrogel at +0.7 V (vs. Ag/AgCl),<sup>4</sup> although efforts must be made to obtain high current densities at potentials which are applicable to EFC technology.

This paper presents a range of naphthoquinone analogues that are capable of mediating electron transfer between FAD-GDH and carbon electrodes, with onset potentials ranging between -425 to -150 mV (vs. SCE), at pH 7.4. A naphthoquinone derivative was rationally designed to yield a naphthoquinone redox hydrogel and direct enzyme labeling. Both methods demonstrated large catalytic current densities at low onset potentials. When coupled with an O<sub>2</sub>-reducing biocathode (bilirubin oxidase, direct electron transfer-type) the glucose/O<sub>2</sub> EFC possessed a large open-circuit potential (OCP) of 0.864 mV and was able to deliver a maximum current density of 5.4 mW cm<sup>-2</sup>. The EFC reached its maximum power density (2.3 mW cm<sup>-2</sup>) at 0.55 V.

Cytochromes *c* (cyts *c*) are heme-bearing redox-active proteins that have at least one covalently tethered protoporphyrin IX cofactor that is attached to the protein via two cysteine (Cys) residues found in a CXXCH sequence motif. Multi-heme cytochromes *c* contain multiple heme cofactors, where the resulting metalloproteins have been implicated in long-range electron transfer in “electronic” microbes and as multi-electron redox catalysts. Here, a series of vignettes depicting the trials and tribulations using protein electrochemistry and bioinformatics will be presented in the context of bacterial cytochromes *c*, spanning tetraheme cytochrome *c*<sub>554</sub> and its orthologs, to more complex enzymes such pentaheme cytochrome *c* nitrite reductase from *Shewanella oneidensis*. In the case of orthologs of cytochrome *c*<sub>554</sub>, a presumed core protein-fold and placement of four heme cofactors has been analyzed in the context the remarkable ability of *Nitrosomonas europaea* cyt *c*<sub>554</sub> to engage in apparent cooperative electron transfer across the protein structure. Using a recombinant *Ne* cyt *c*<sub>554</sub> construct, and newly discovered orthologs of this metalloprotein family, we examine the issues surrounding cooperativity – ie, how Nature takes two one-electron units and persuades them to do two-electron chemistry. Interfacial electron transfer rate and inter-cofactor arrangement are key determinants in whether cooperativity is observed or not. In the case of cytochrome *c* nitrite reductase (ccNiR), complex electrocatalytic signatures of the enzyme reducing nitrite will be used to address the mechanism of ccNiR catalysis. We find that despite the pentaheme nature of the enzyme, electrocatalysis proceeds in via a series of one-electron steps, and that only some of these steps are linked to proton-transfers. A series of mutations in close proximity to the active site allows for determining  $pK_a$  values for the catalytic electron transfer steps, and yields a new view of the multi-electron chemistry catalyzed by the enzyme in action. Here, the proposed mechanism of nitrite reduction to ammonia will be evaluated in the context of the electrocatalytic data. Finally, efforts to understand the diversity of reactivity observed in multiheme cytochromes *c* will be presented. Although multi-heme cytochromes *c* contain multiple CXXCH motifs, the diversity of their function (provide either specific redox partners, general electron transfer pathways, or catalysts for either oxidative or reductive chemistries) has yet to be understood in a rigorous way. Here, we will examine this diversity in the context of a sequence similarity network approach, and correlating the bioinformatics analysis to known redox properties.

# Electrocatalytic cascades driven by enzymes and metal nanoparticles on carbon supports: the reduction of nitrate to ammonia at neutral pH

The treatment of nitrate-laden wastewater is a key challenge in Environmental Sciences, calling for improved methods for the selective removal of this polluting ion.

The electrochemical reduction of nitrate is severely limited by a series of significant drawbacks[1]: low catalytic activity at neutral pH (typical of wastewater), and at low concentrations, or interference by other solution species which adsorb more strongly. These limitations do not affect biological catalysts, such as the enzyme nitrate reductase (Nar); direct electrochemistry has been demonstrated for one (*E. coli* NarGHI) immobilized onto a graphite electrode [2]. In this way, NarGHI functions as an electrocatalyst for the reduction of nitrate in a broad pH range ( $5 < \text{pH} < 9$ ) and at sub-millimolar concentrations. The reduction of nitrite is the following step in denitrification, occurring at noble metal electrodes even at neutral pH, but with diminishing catalytic activity at pH values in the range 6-8.

In this study, NarGHI and noble metal nanoparticles have been combined to assemble a composite electrode capable of reducing nitrate to ammonia at neutral pH [3]. NarGHI is immobilized onto high-surface area carbon particles, mixed with commercial carbon-supported Pt, Rh or Pd nanoparticles and deposited onto a pyrolytic graphite “edge” electrode (PGE), thus allowing potential control of the two catalysts simultaneously. When this composite electrode is immersed in a pH 6.1 phosphate buffer solution containing 1 mM NaNO<sub>3</sub>, NarGHI selectively performs the reaction  $\text{NO}_3^- \rightarrow \text{NO}_2^-$  at a potential close to 0.1 V vs SHE. As the potential is decreased, NO<sub>2</sub><sup>-</sup> produced *in situ* can be further reduced to NH<sub>4</sub><sup>+</sup> by the metal nanoparticles. ATR-IR spectroscopy has been used to study intermediates in the catalyst layer, while rotating-ring disk and photometric methods have been employed to study the product distribution after constant-potential reduction and how it is affected by varying the ratio of the two catalysts.

This study opens up a new approach to the fabrication of composite electrode able to overcome the intrinsic limitations of the individual catalysts used.

The electrical connection of enzymes and microelectrodes is usually achieved via the direct deposition of biomolecules at the electrode surface. Optimization of this interface can be done either by using conductive nanomaterials such as carbon nanotubes, by adding shuttles of electrons and/or by tuning the geometry of the electrode. However, immobilized enzymes remain essentially located at the outer surface of the electrode, limiting therefore the current density of the devices.

We developed a single step and scalable fiber wet-spinning approach that allows the fabrication of microfibers into which enzymes and carbon nanotubes are imbricated in the core of the fiber. Their efficiency is tested against the enzymatic reduction of O<sub>2</sub> using bilirubin oxidases (BODs) as enzyme. The delicate combination and formulation of CNTs and BODs allowed the development of a new wet spinning process to produce efficient enzymatic hybrid bioelectronics for the reduction of O<sub>2</sub>. A 7 fold increase in current density is reached compared to conventional coating method while preserving all the advantages of microelectrodes in terms of miniaturization and spatio-temporal resolution. This significant improvement is ascribed to the large amount of enzyme immobilized in the core of the fibers.

The present approach could also be extended to other enzymes and finally the scalability of the fiber wet-spinning method would be a valuable advantage for future applications.

# Monitoring Electrochemically the Early Events of Hydrogen Peroxide Production by Mitochondria

Mitochondria are the site of metabolic transformation of organic substrates into the energetic ATP. The respiratory chain couples electron transfers to proton transport used by ATP synthases (namely, the OXPHOS process). The final electron acceptor of the respiratory chain is oxygen converted into water. However, it is demonstrated that the respiratory chain is also producing reactive oxygen species (ROS), involved either in signaling pathways or in oxidative stress. Dysregulation of mitochondria metabolism leads to severe pathological processes (myopathies, neurodegenerative diseases...).

We have developed an electrochemical biosensor to monitor quantitatively and kinetically the production of a ROS, hydrogen peroxide, by mitochondria. Our approach consist in embedding horseradish peroxidase (HRP) in a cross-linked 3D-polymer matrix bearing mobile osmium-based redox ( $\text{Os}^+ / \text{Os}^{2+}$ ) moieties. We optimized the ratio between components (HRP/polymer/cross-linker) and the whole loading on electrode surface, so as to reach high analytical performances: specific amperometric detection of  $\text{H}_2\text{O}_2$  at +0 V vs. Ag/AgCl, 1 nM LOD for  $\text{H}_2\text{O}_2$ , and a linear response over 5 concentration-decades.

These bioelectrodes allowed monitoring the release of  $\text{H}_2\text{O}_2$  by mitochondria (yeast origin) under several conditions (phosphorylating, inhibited respiration...). We report the detection of two concomitant regimes of  $\text{H}_2\text{O}_2$  release: large fluxes (hundreds of nM) under complex III-blockade, and bursts of a few nanomolars and few min.-duration immediately following mitochondria activation. These bursts of  $\text{H}_2\text{O}_2$  match superoxide flashes observed by fluorescence, and can be assigned to the role of mitochondria as the central hub of redox signaling in cells.

**Figure:** Detection principle of Hydrogen peroxide release by mitochondria during oxidative phosphorylation. Nanomolar bursts of  $\text{H}_2\text{O}_2$  by energized mitochondria were detected (red curve on right) owing to a bioelectrode (HRP/Osmium based redox polymer/carbon electrode).

Bioluminescence is the light emitted by living organism via some reactions<sup>[1]</sup>. The bacterial luminescence mechanism was proposed that the luciferase can oxidize the reduced form of flavin mononucleotide (FMNH<sub>2</sub>) using molecular oxygen to generate blue-green light, as shown in equation 1<sup>[2]</sup>. Therefore, FMNH<sub>2</sub> is one of the key substrates for the bioluminescence production. It is widely accepted that the fully oxidized flavin (FMN) can be reduced to FMNH<sub>2</sub> in “one step” with a 2e<sup>-</sup>/2H<sup>+</sup> reduction by applying a reducing potential in aqueous media<sup>[3]</sup>. Therefore, we supposed that the bioluminescence may be affected by the redox reaction of FMNH<sub>2</sub> controlled by electrode.

Herein, *Shewanella woodyi*<sup>[4]</sup> was cultured in 2216E medium at 25°C with 150 rpm shaking. The growth curve and luminance were recorded by OD<sub>600nm</sub> and fluorescent imaging system, respectively. As shown in Fig.1(a), *S. woodyi* showed the highest luminescence when it was cultured for 30 h which corresponds to the beginning of stable phase. *S. woodyi* is electrochemical active bacterium based on CV results. Besides, the electrochemical bioluminescence response of *Shewanella woodyi* was successfully regulated on the ITO/suspension interface at the potential range of -0.6 V ~ 0.4 V, which can reduce and oxidize FMN to FMNH<sub>2</sub> along with the change of potential.

**Figure 1** (a) growth curve and bioluminescent intensity of *Shewanella woodyi* cultured at 25°C (b) CV and corresponding electrochemical bioluminescence response of the bacterial suspension which cultured for 28 h.

This work was supported by National Science Foundation of China (Grant No. 21273180).

# Manipulation of biomolecular functions at electrode surfaces via surface modification

Xing-Hua Xia

*State Key Laboratory of Analytical Chemistry for Life Science, School of Chemistry and Chemical Engineering, Nanjing University, Nanjing 210093, China  
e-mail: xhxia@nju.edu.cn*

Immobilization of proteins and enzymes on electrode surfaces plays an important role in determining the orientation, conformation, direct electron transfer and related biocatalytic activity. We used surface enhanced infrared absorption spectroscopy (SEIRAS) and electrochemical techniques studied the influence of surface properties on adsorption, orientation, conformation and related DET and biocatalytic activity of immobilized proteins.

First, the adsorption kinetics of cytochrome c on a nanostructured gold film will be discussed. Following the evolution of amide I and amide II bands with time, the adsorption kinetics of the protein can be explained by the Freundlich model. Then, COOH, OH and CH<sub>3</sub>-terminated thiols have been self-assembled on the nanostructured Au films. With COOH-terminated SAM, the surface electric field can be manipulated by pH, and the influence of electric field on the DET of cytochrome c on this SAM was studied. We then used the OH and CH<sub>3</sub>-terminated SAMs to immobilize cytochrome c and studied the influence of surface wettability on the DET of cytochrome c. It showed that DET of cytochrome c occurs when the heme plane is parallel to the hydrophilic SAM/gold surface, while it is forbidden if the heme plane is perpendicular to the hydrophobic SAM/gold surface, although the secondary structure of immobilized cyt c is the same on both SAMs.

## **Abstract**

Graphene (GR) based nanocomposites are very effective electrocatalyst towards biomolecules and toxic pollutants because of their stability, high mass transfer and relatively large surface areas. The electrode materials were characterized by cyclic voltammetry, X-ray photoelectron spectroscopy, high-resolution transmission electron microscopy, field-emission scanning electron microscopy, energy-dispersive X-ray spectroscopy and X-ray diffraction studies. Firstly, GR/cobalt oxide nanoparticles ( $\text{Co}_3\text{O}_4\text{-NP}_s$ ) have been used for the immobilization of glucose oxidase (GOx) to construct the glucose biosensor and also developed  $\text{H}_2\text{O}_2$  sensor. The prepared GR nanosheets/polyethyleneimine/gold nanoparticles (GNS/PEI/AuNPs) composite film exhibited excellent electrocatalytic activity towards the selective determination of dopamine in the presence of ascorbic acid and also demonstrated for the determination of dopamine in human urine samples. In addition, the electrodeposition of calcium ions cross linked pectin (CCLP) stabilized AuNPs on GR modified electrode have significantly enhanced electrocatalytic ability towards oxidation of hydrazine. The fabricated GR based nanocomposites have shown excellent analytical parameters towards biomolecules and toxic pollutants.

# Improving the Electrochemical Measurement Sensitivity of SECM-SICM by using Pt Electrodeposited Carbon Nanoelectrode

Scanning electrochemical microscopy (SECM) uses an electrode tip for detecting electroactive chemical species and is an effective tool for the investigation of the localized chemical properties of sample surfaces and interfaces. We have developed nanoelectrode and electrode-sample distance control system to improve SECM resolution<sup>1,2,3</sup>, and to insert the electrode into cell for intracellular measurement<sup>4</sup>. Although SECM imaging with nanoelectrode provides high spatial resolution, chemical sensitivity is usually lost. The amperometric detection of 1  $\mu\text{M}$  of electroactive species by using a 3  $\mu\text{m}$  radius microelectrode produces about 1 pA current level, which is limit of the electrochemical detection for conventional current amplifier. To perform a highly sensitive electrochemical measurement while maintaining the spatial resolution of the SECM, it is necessary to increase the size of the electrode locally.

Here, we report the size controllable Pt electrochemical deposition electrode to improve sensitivity of electrochemical measurement. For electrode accurate position control, we used ion current feedback distance control, which is used in a scanning ion conductance microscopy (SICM). We compared a bare carbon electrode with Pt-deposited electrode based on the electrochemical sensitivity and imaging quality<sup>5</sup>. Figure 1 shows the images of immunocytochemically stained EGFR proteins on A431 cells. The current response of SECM image with the Pt-deposited electrode was almost 6 times larger than that for the bare carbon electrode. This result indicates the Pt-deposited electrode is useful to image of low concentration chemical around a single cell.

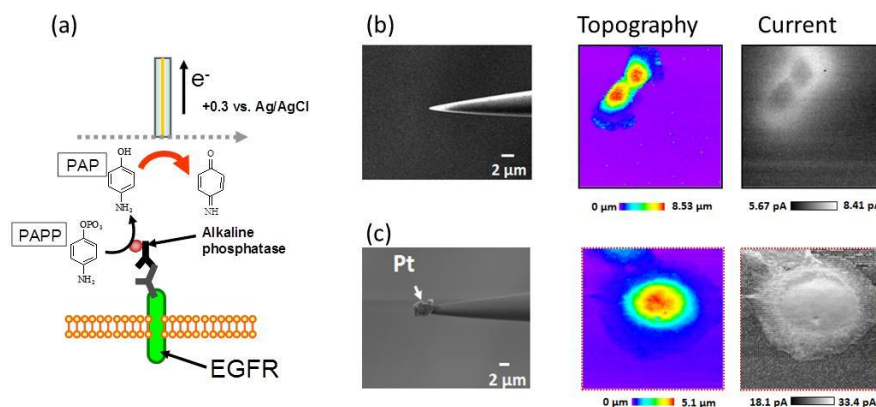

Figure 1 (a) Schematic illustration membrane protein imaging using SECM. SEM images of (b) bare carbon and (c) Pt-deposited electrode probe ( $-10$  nA of final deposition current) in 1 mM of  $\text{FcCH}_2\text{OH}$ +PBS. Topographic and electrochemical images of A431 cells in 4.7 mM PAPP using (b) bare carbon and (c) Pt-deposited probes. SECM and SICM electrodes were held at +0.3 and +0.2 V vs Ag/AgCl, respectively. (The scanned areas are (b)  $80 \times 80 \mu\text{m}$  and (c)  $50 \times 50 \mu\text{m}$ .)

Hydrogen enzymatic biofuel cells (EBFC) are based on hydrogenases and multicopper oxidases for H<sub>2</sub> oxidation and O<sub>2</sub> reduction, respectively. Their development just emerged because of the recent identification and characterization of hydrogenases able to tolerate oxygen while being efficient H<sub>2</sub> oxidizers. We especially identified in the ancestral bacterium *Aquifex aeolicus* a hyperthermophile hydrogenase tolerant to O<sub>2</sub> and insensitive to CO [1]. Based on this hydrogenase and *Myrothecium verrucaria* bilirubin oxidase (BOD), both covalently grafted on carbon nanotubes, we designed two years ago a hydrogen EBFC delivering 300  $\mu\text{W}\cdot\text{cm}^{-2}$  [2]. This first biodevice allowed defining the main limitations to be overcome before enabling practical applications. On one hand, enhancement of the amount of electrically connected hydrogenases was required. On the other hand, there was a need for a thermostable O<sub>2</sub>-reducing enzyme in order to take benefit of the hyperthermophily of *A. aeolicus* hydrogenase.

We present in this work a new generation of H<sub>2</sub>/O<sub>2</sub> EBFC able to deliver more than 1 mW/cm<sup>2</sup> over a temperature range from 30 to 70°C. These performances are linked to the direct wiring of two thermostable enzymes in fishbone nanofiber mesoporous films, i.e. *A. aeolicus* hydrogenase and *Bacillus pumilus* BOD [3-5]. We discuss the performances of this EBFC as a function of carbon nanostructure, mass transport, temperature and pH.

Thanks to an efficient direct electron transfer between *B. pumilus* and carbon nanofiber-modified electrode, we investigate the catalytic mechanism of O<sub>2</sub> reduction in the presence of NaCl, and discuss the conditions of formation of an enzyme state only active after being reduced at low potentials [6]. Because BODs have been preferred to chloride sensitive laccases to be used for the elaboration of biocathodes, these new findings will have consequences for other devices than hydrogen EBCFs such as sugars/O<sub>2</sub> implantable biofuel cells.

# **Amyloid $\beta$ Peptides Nanostructures: Voltammetric and Atomic Force Microscopy Characterization**

Ana Maria Oliveira-Brett, A.M. Chiorcea-Paquim, T.A. Enache  
*Department of Chemistry, University of Coimbra, 3004-535 Coimbra, Portugal*  
*brett@ci.uc.pt*

Alzheimer's disease (AD), the most common form of dementia, is an incurable, progressive, and terminal neurodegenerative disease. The AD brain histopathology is characterized by the presence of intracellular neurofibrillary tangles of hyperphosphorylated tau proteins and by extracellular amyloid plaques containing a mixture of amyloid  $\beta$  ( $A\beta$ ) peptides of approximately 40 amino acids, having different N- and C- termini, generated from a larger amyloid  $\beta$  protein precursor ( $A\beta$ PP) through proteolytic cleavage of  $\beta$  and  $\gamma$  secretases.

Since  $A\beta$  peptides participate in redox reactions in the extracellular medium, the aim of the present study was the investigation of the  $A\beta$  peptides direct electron transfer processes.

Different length, native and mutant,  $A\beta$  monomer structures were systematically studied by cyclic and differential pulse voltammetry, at a glassy carbon electrode, and by AFM, on the surface of highly oriented pyrolytic graphite, to elucidate the redox behavior and the adsorption mechanisms, with respect to the  $A\beta$  peptides ability to form protofibrils and fibrils, to large aggregated structures.

The  $A\beta$  monomers,  $A\beta$ 01-40 and  $A\beta$ 01-42, contain five electroactive residues: three histidines (H6, H13 and H14), one tyrosine (Y10) and one methionine (M35).

At physiological pH 7.4 the most easily detected amino acid was tyrosine, followed by histidine. Methionine oxidation occurred at a higher potential.

The investigation of the  $A\beta$  peptides direct electrochemical oxidation mechanisms, in solution and adsorbed at the electrode surface, provided valuable insights into biological redox reactions of this class of molecules, resulting in a better understanding of mechanisms in which different fragments and mutants aggregate at different rates and by different pathways.

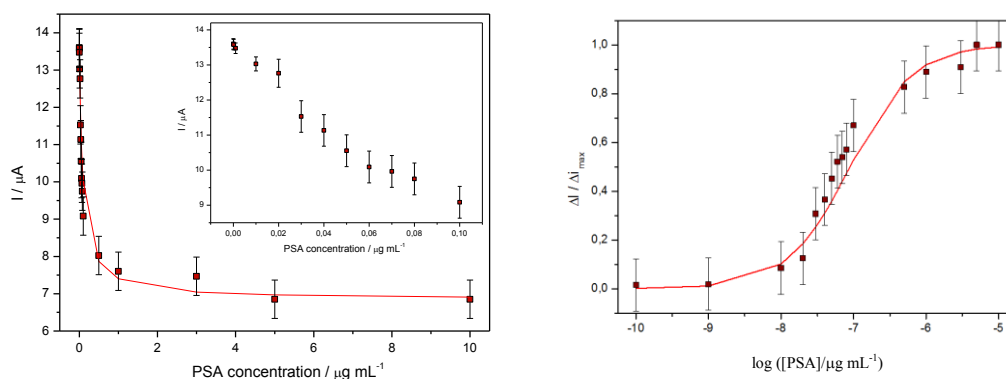

Atomic force microscopy was capable of characterising features at single-molecular level, providing additional information about the  $A\beta$  peptides fibrillation process.

# Label-free Electrochemical Detection of Prostate-Specific Antigen based on Nucleic Acid Aptamer

B. Piro, M. Souada, S. Reisberg, G. Anquetin, V. Noël, M.C. Pham  
Univ. Paris Diderot, Sorbonne Paris Cité, ITODYS, UMR 7086 CNRS,  
15 rue J-A de Baïf, 75205 Paris Cedex 13, France  
piro@univ-paris-diderot.fr

For detection and quantification of proteins such as prostate specific antigen (PSA, a biomarker of prostate cancer) with high affinity and specificity, immunosensors have been thoroughly investigated. However, if the immunologic approach is mature, non-immunologic ones were poorly investigated. Recently, nucleic aptamers (nucleic acid strands having recognition properties toward other molecules than DNA, such as organic molecules or proteins) appeared as promising alternatives to antibodies, due to their ease of production. Aptamers were initially developed for targeting cancer cells; they only appeared in the literature dedicated to analytical chemistry in the middle of the 2000s. Since, most works have focused on a model protein, thrombin. Among various transduction techniques, electrochemistry has been extensively investigated using redox labels, redox intercalators or even label-free, but there is still very few literature dealing with PSA. The first publication on PSA detection used nanostructured mesoporous electrodes, a biotin-streptavidin immobilizing strategy and hexacyanoferrate added in solution as redox reporter, with a LoD in the  $\text{ng mL}^{-1}$  range [1]. Another work reported a sandwich-type electrochemical biosensor based on gold electrodes modified with aptamers. The captured PSA was then derivatized with gold nanoparticles carrying a redox tag, followed by voltammetric detection. A sub-picomolar LoD was determined for this elaborated multi-step procedure [2].

We report in this work a label-free electrochemical aptasensor (no need to add redox label or redox molecule in solution) featuring a DNA aptamer having an excellent affinity for PSA ( $K_D$  in the nM range) [3]. The immobilized redox reporter is a quinone-modified electrode onto which the anti-PSA aptamer is grafted. PSA being a significantly heavier molecule than the aptamer, its capture hinders the polymer/electrolyte interface, therefore causes a decrease of the redox current intensity (“signal-off”), measured by Square Wave Voltammetry. This current decrease is specific for PSA above a limit of quantification in the  $\text{ng mL}^{-1}$  range ( $\sim 300$  pM). We have shown that this can be switched to a current increase (“signal-on”) by subsequent hybridization of the aptamer with its complementary DNA strand added in solution, which breaks PSA-aptamer interactions. This *on-off* procedure is a way to estimate the specificity of the system in order to avoid false positives. The PSA-aptamer dissociation constant  $K_D$ , of ca. 2.6 nM, was determined by this electrochemical method.

**Figure 1.** (a) Peak current of SWVs in PBS of a poly(JUG-co-JUGA)/Apta electrode as a function of PSA concentration (Inset: concentrations from 1 to 100  $\text{ng mL}^{-1}$ ). (b) Corresponding isotherm giving  $K_D = 2.6$  nM ( $89$   $\text{ng mL}^{-1}$ ) for PSA concentrations from 1  $\text{ng mL}^{-1}$  to 10  $\mu\text{g mL}^{-1}$ . Pulse height 50 mV, scan increment 2 mV, 12.5 Hz. Curves correspond to fit with the Langmuir isotherm.

Enzymatic H<sub>2</sub>/O<sub>2</sub> biofuel cells (BFC) recently emerged as attractive devices for small power applications [1]. In this “green” fuel cell, biocatalysts would replace chemical catalysts both at the anodic and cathodic sides. We previously identified and purified a hyperthermophile [NiFe] hydrogenase with outstanding properties compared to classical [NiFe] hydrogenases. We proved it is very efficient for oxidizing H<sub>2</sub> over a large range of temperatures from 25 to 80 °C and is tolerant to O<sub>2</sub> and completely insensitive to CO [2]. Coupled to a very efficient cathode based on the thermostable bilirubin oxidase from *Bacillus pumilus* (Bp BOD), a BFC was recently designed delivering 1.5 mW.cm<sup>-2</sup> at 0.6 V over a range of temperature from 30 to 80 °C [3].

One of the main challenges to enzymatic biofuel cells is to achieve higher performances and stability in order to become a self-sufficiency source of energy. H<sub>2</sub>/O<sub>2</sub> biofuel cells based on fish bone carbon nanofibers (CNFs) have proved that three main key challenges on enzyme immobilization have to be overcome: 1- Carbon nanofiber film stability on planar graphite electrodes which limits the available interacting surface; 2- substrate transport limitation through the mesoporous material; and 3- stability of the bio hybrid over time [3]. Recently we explored two different ways to overcome of these limitations of biofuel cell set-ups. We showed that gold nanoparticle can serve as efficient platforms for hydrogenase immobilization [4]. The long-term stability of the biohybrid was shown to be enhanced. We also designed a H<sub>2</sub>/O<sub>2</sub> BFC with an air-breathing cathode [5]. We present in this work, new strategies based on enzymes entrapped in carbon felt-based materials which act as enzyme host matrices with no need of additional electron collector. Microscopy and electrochemical probes experiments will be carried out to characterize the carbon support. Catalytic oxidation of H<sub>2</sub> and reduction of O<sub>2</sub> will be analyzed using electrochemistry in terms of enzyme grafting, influence of carbon material modification with different nano-materials and biopolymers. Electrochemical analysis of the biohybrid stability will be linked to quantification of enzyme release and/or denaturation. Finally, we will develop a H<sub>2</sub>/O<sub>2</sub> BFC demonstrator with the power cell efficiency required to feed a wireless electronic device.

# Facile optimization of gold nanostructures for high SERS intensity by means of bipolar electrochemistry

Vera Eßmann, Yasin Uğur Kayran, Daliborka Jambrec, Adrian Ruff, Stefanie Grützke, Wolfgang Schuhmann

Analytical Chemistry - Center for Electrochemical Sciences (CES); Ruhr-Universität Bochum, Universitätsstr. 150; 44780 Bochum; Germany  
vera.essmann@rub.de

Surface enhanced Raman spectroscopy (SERS) is a very powerful and versatile analytical tool able to detect even single molecules.<sup>1</sup> When inducing surface plasmons at a metal surface with light, Raman signals can be intensified due to an amplification of the localized electric field. The enhancement occurs predominantly at so-called “hot spots” such as nanoscale junctions between suitable metallic structures like silver or gold nanoparticles or -voids.

Here, we present a simple and fast approach for the fabrication and selection of nanostructures that lead to very high SERS intensities by means of bipolar electrochemistry. The process is based on the preparation of a size gradient of gold nanovoids on a single electrode (see figure). First, the gold electrode was coated with a 2D crystal of polystyrene (PS) nanobeads using a Langmuir trough. Then a potential gradient across the nanobead-modified surface enables wireless and gradual electrodeposition of gold leading to a gradient of nanovoid sizes after removal of the PS beads. This allows for the determination of the optimal nanostructures and thus the optimal deposition potential for highest SERS signals by using only a single bipolar electrode. A correlation between the nanovoid dimensions and the SERS intensity was observed employing an adsorbed Raman reporter molecule.

Furthermore, the nanovoid SERS substrates were evaluated with respect to the detection of DNA hybridization. In dependence on the nanovoid characteristics, double-stranded DNA could be distinguished from the single-stranded probe DNA via a label-free approach using a Raman-active DNA intercalator.<sup>2</sup>

Schematic illustration of the size gradient of nanovoids on a gold surface and the label-free approach for detection of dsDNA via SERS.

daliborka.jambrec@ruhr-uni-bochum.de

During the course of the DNA immobilization process on gold surfaces via the incubation of the DNA, grafting of subsequent strands becomes energetically unfavourable due to the increasing electrostatic repulsion between the strands. Consequently, depending on the desired DNA coverage, the immobilization process using the incubation method can last from a couple of hours to days. We present a new potential-assisted immobilization method that overcomes this limitation and significantly accelerates the immobilization process by pulse-type modulation of the potential applied to the electrode surface during the immobilization process.

The manipulation of the DNA in the vicinity of electrified interfaces by potentials applied to the electrode surface is attracting increasing attention<sup>1</sup>. It was reported that potentials more positive than the potential of zero charge (pzc) cause bending of the grafted DNA towards the surface, while negative potentials favor an upright orientation of the immobilized DNA strands<sup>2</sup>. Furthermore, previous attempts aiming at the potential-assisted DNA immobilization itself, which took pzc into consideration, referred to the pzc of the bare electrode<sup>3</sup>. It was reported, that due to the applied potential the DNA strands are attracted or repelled during the course of the immobilization process.

We will present a new model for the potential-assisted immobilization of DNA at gold electrodes that considers the role of counterions surrounding the DNA, the distance from the electrode surface to which applied potentials have an effect and the shift of the pzc during the course of the immobilization due to the surface modification with DNA. Furthermore, we show the importance of choosing suitable potentials with respect to the pzc to obtain the optimal immobilization yield. By taking into account the proposed model, we obtained a highly reproducible potential-assisted immobilization method that is much more efficient and much faster than the standard incubation method.

# Scanning electrochemical microscopy of adherent melanoma cells: alive, fixed and permeabilized

Alexandra Bondarenko,<sup>a</sup> Tzu-En Lin,<sup>a</sup> Horst Pick,<sup>b</sup> Andreas Lesch,<sup>a</sup> Fernando Cortés-Salazar<sup>a</sup> and Hubert H. Girault<sup>a</sup>

<sup>a</sup> Laboratoire d'Electrochimie Physique et Analytique (LEPA), EPFL, Lausanne, Switzerland

<sup>b</sup> Laboratoire de Chimie Physique des Polymères et Membranes (LCPPM), EPFL, Lausanne, Switzerland  
alexandra.bondarenko@epfl.ch

Scanning electrochemical microscopy (SECM) is a surface reactivity characterization technique based on an electrochemical signal recorded at a probe positioned or scanned in close proximity to a substrate<sup>1</sup>. Thanks to its high spatial resolution and versatility, SECM has demonstrated to be a useful tool for the electrochemical imaging and intracellular investigation of different living cells types including mammalian cells<sup>2</sup>. However, the interpretation of the experimental data obtained from living cells can be difficult due to i) cell to cell variability in terms of metabolic activities and simultaneously occurring different biological processes, ii) possible dynamic morphological changes of cells due to cell mobility and iii) experimental time restrictions (e.g. experimental buffer solutions and redox mediators can be toxic for cells during long term experiments). Alternatively, working with fixed cells (e.g. after treatment with paraformaldehyde and/or methanol) leads to the elimination of biological activity of adherent cells, but opens the opportunity to access more easily the preserved cellular ultrastructure as well as proteins, carbohydrates and other bio-active moieties in their original spatial organization within the cells. Whereas paraformaldehyde crosslinks cellular proteins but does not permeabilize the plasma membrane, methanol fixation is based on proteins precipitation and partial dissolution of lipids resulting in membrane pores formation<sup>3</sup>. The paraformaldehyde fixation can be used for SECM to investigate the topography or the passive transport of the redox mediator through the membrane in a constant height scanning mode for any type of redox mediators while the methanol fixation can open the intracellular compartment to be analyzed by the scanning ultramicroelectrode (Figure 1a).

In this contribution, different melanoma cell lines representing progressive stages of skin cancer development (SBC12, non-invasive radial growth phase; WM115, vertical growth phase; WM239, metastatic) were studied by SECM in the feedback mode. The data were collected for living cells, cells fixed with formaldehyde and cells fixed with methanol. Depending on the employed cell fixation procedure cells were able to provide both positive and negative feedback by using the same redox mediator based on the ability of the redox mediator to access the intracellular space and to react with electrochemical active species (Figure 1b). For a better understanding the nature of the feedback signal, the influence of the redox mediator type (charged or non-charged), the ultramicroelectrode size and the probe translation speed were investigated. Furthermore, the permeabilization of cell membranes during the methanol fixation process was employed to compare the tyrosinase expression in different melanoma cell lines by immunostaining. With this aim, fixed melanoma cells were incubated with primary antibodies (Ab) and secondary Ab conjugated with horseradish peroxidase. The enzymatic activity was then readout by SECM in the substrate generation – tip collection mode.

**Figure 1.** (a) Schematic representation of cells fixation with formaldehyde and methanol and the information which can be obtained during the SECM experiments in each case and (b) electrochemical signal recorded during line-scans above the same cells fixed with formaldehyde (black) and methanol (red) using 1 mM  $\text{K}_3\text{IrCl}_6$  as redox mediator. The current  $I$  was normalized by the current  $I_0$  above the Petri dish surface. The working distance  $d$  was equal to 25  $\mu\text{m}$ . Exp. Conditions: applied potential at a Pt UME 1 V; diameter 25  $\mu\text{m}$ , RG 3.5, CE Pt, QRE Ag.

The level of creatinine in human serum is an important and useful indicator for monitoring the function of people's kidney. Many creatinine biosensors have been developed based on tri-enzyme system for converting creatinine to creatine, creatine to sarcosine and sarcosine to glycerine with the various enzymes [1]. The tri-enzyme creatinine biosensor is designed to sensing the level of oxygen consumed or hydrogen peroxide generated in enzyme reactions. However, the level of creatinine can be determined by analysis the concentration of ammonium ion (product of enzymatic hydrolysis of creatinine by creatinine deiminase) for the monoenzymatic creatinine biosensor [1]. Using PANI (polyaniline)-Nafion/Au/Al<sub>2</sub>O<sub>3</sub> prepared by cyclic voltammetry (CV) with cycle number of 5 as sensing electrode, the sensitivity of ammonium ion sensor is obtained to be 100.4  $\mu\text{A mM}^{-1}$ . The nano-structured PANI-PSSMA (poly(styrene sulfonate-co-maleic acid)/Au/Al<sub>2</sub>O<sub>3</sub> prepared by chronopotentiometric technique is also used to sensing the concentration of ammonium ion. The sensitivity of amperometric ammonium ion sensor is increased by increasing the amount of PSSMA and decreasing temperature for preparing PANI-PSSMA composite film. The maximum sensitivity of amperometric ammonium ion sensor based on PANI-PSSMA/Au/Al<sub>2</sub>O<sub>3</sub> is found to be 126.2  $\mu\text{A mM}^{-1}$ . The amperometric monoenzyme creatinine biosensing electrodes are fabricated by immobilizing creatinine deiminase onto PANI-Nafion/Au/Al<sub>2</sub>O<sub>3</sub> and nano-structured PANI-PSSMA/Au/Al<sub>2</sub>O<sub>3</sub>. The surface morphologies of the sensing electrode are analyzed by FESEM. The sensing properties of monoenzyme creatinine amperometric biosensors are systematically investigated in this work.

yasuzawa@tokushima-u.ac.jp

Recently, several types of implantable glucose sensors for continuous glucose monitoring (CGM) are available in the market and have provided significant benefit on the management of diabetic health care. The big advantage of CGM is that it will present not only the point of glucose degree but also its trend. The recognition of distinct rising or lowering of blood glucose may lead to an opposite treatment even the glucose level was same on its point. Moreover, daily trend observation is useful for the evaluation and improvement of individual pharmacotherapy. However, since sensor device of CGM at a present day requires a length of 1 cm to be inserted in skin, development of lower invasive CGM system is expected for the improvement of diabetic patients' quality of life.

In this study, a fine needle tube type glucose sensor, which has sensing region at the tip of a fine tapered electrode, was proposed. Since the sensing region is at the tip of tapered electrode, it only requires the sensor tip to be implanted in the tissue for glucose monitoring. In other words, it can be possible to perform as a patch type sensor, which impresses the user as a sticking sensor instead of a implanting sensor. Fine platinum-iridium alloy wire with a diameter of 0.17 mm was placed inside the tapered PEEK tube and glucose oxidase (GOx) was immobilized on the surface of platinum electrode by using the combination of electrodeposition and electropolymerization technique, which was similar to the procedure proposed by Wilson's group [1,2]. Glucose sensor properties of the obtained GOx-immobilized electrode were evaluated mainly by in vitro measurement.

The response current of the obtained electrode increased with increasing concentration of glucose up to 21.6 mM. Response current provided good linear relationship with glucose concentration. Correlation coefficient of 0.988 was obtained ranging up to 21.6 mM. Variation of response in time on the prepared electrode was investigated for two weeks. The response of the electrode was measured at 40°C and stored in phosphate buffer at 4°C when not in use. After an initial increase of response current for few days, the electrode provided stable response current.

Hydrogen peroxide is an important marker in the biomedical reactions, and it is a kind of electroactive species which could be detected using electrochemical techniques. In the previous studies, graphene-based material has been extensively applied for electrochemical sensors [1], and it showed high sensitivity. In order to improve the selectivity, some electrocatalysts were introduced for lower the operating potential such as Pr, Au and Ir [2]. Although graphene-based materials are promising for sensing, it is not so easy to deposit metal onto the surface due to the lack of functional group for the reaction.

In this study, the high functional group density of graphene oxide was exploited as the substrate for the nanoparticles deposition. A highly sensitive nonenzymatic hydrogen peroxide ( $H_2O_2$ ) sensor was fabricated based on Iridium Nanoparticle/Graphene Oxide (Ir NP/GO) nanocomposites. The nanocomposites were rapidly synthesized via a one-step hydrothermal technique. The synthesized composites were characterized by X-ray diffraction (XRD), transmission electron microscopy (TEM), Fourier Transform Infrared Spectroscopy (FTIR) and X-ray photoelectron spectroscopy (XPS).

The TEM results indicated that Ir nanoparticles (IrNPs) distributed on the graphene surface uniformly with the average diameter of around 2.0 nm. We have found the operating potential of IrNP/GO was lower than that of GO. It implied the decorated IrNP catalyzed  $H_2O_2$  electrochemical oxidation reaction. It also showed high sensitivity to  $H_2O_2$  at low concentration and the detection limit was lower than 0.1 nM. Since the oxidation state might altered the morphology of IrNP/GO and the sensing performance, the effect of the oxidation state was studied. The sensitivity, reproducibility and the selectivity were evaluated. On the other hand, the effect of pH value and operating temperature was accessed as well in the sensing process. A highly sensitive platform of IrNP-GO for  $H_2O_2$  sensing was developed successfully.

Early and fast diagnosis and prognosis of heart injury and cancer pathologies are of paramount importance for a successful treatment of the diseases. Furthermore, cancer related pathologies, also caused by anticancer treatment, are determinant in cancer patient survival. Several molecular markers of heart damage and cancer are emerging and electrochemical driven trapping, detection and signal transduction of biomarkers have proven to be profitably employed in the development of sensing biochips and assays.

For instance, cytochrome c (cyt c) is an inner mitochondrial membrane (IMM) protein, which plays an important role in oxidative phosphorylation. This protein is not detectable in healthy patients' blood but it has been demonstrated that during some diseases, which involves the cellular apoptosis, cyt c is released [1]. In particular, cyt c is released from cellular membrane as a consequence of the treatment of infarction.[2] A fast monitoring of cyt c concentration can help to control the progression and extension of the heart injury guiding the therapeutic actions.

In this view, there is an urgent need to develop biochips/sensors/devices for the rapid detection of markers, such as cyt c, in very early stages of the diseases to evaluate the state and to operate with fast bedside therapies.

Herein, we show some strategies based on optimized chemical affinity for the trapping and the detection of disease markers and for signal amplification.

Recent focus in the field of micro- and nano-sized targeted drug delivery systems, in strategies of its pre-formulation and formulation, is highly oriented on creation of systems for poorly soluble and/or highly unstable substances; reporting it to be the significant arena in pharmaceutical research. [1] Polymer and hydrogel-based materials with incorporated aptamer oligonucleotides are recently present as a particularly promising line for design of targeted delivery systems. These materials have been successfully proposed for several biomedical applications due to its unique dynamical structural properties such: the complementarity rule, denaturation, annealing, hybridization, conformation. [2,3]

In our work, we would like to present the synthesis and optimization steps needed for preparation of nanostructure materials designed from PNIPA, PAA, PEG hydrogels and DNA oligonucleotides; for improved delivery of selected anticancer drug – doxorubicin (DOX) and Symadex (C-1311). We synthesized nanostructured hydrogel-based lattices with noncovalently entrapped native ssDNA and dsDNA, as well, several kinds of thermoresponsive nano- and –microparticles with covalently attached selected DNA sequences. The synthesis procedure was carried out by free radical polymerization of the 5' ended acrylic group modified two DNA strands and attachment of third DNA strands to both covalently attached DNA in hybridization process. The physicochemical parameters of new materials as: the amount of incorporated DNA, pore distribution, sizes, zeta potentials, were tested. The main goal was investigations of the ability of particular networks to store and release of doxorubicin, before and after initiation of structural changes of oligonucleotides and volume transition of lattices in function of hyperthermia routinely used in cancer treatment.

The ultimate goal in cancer therapy remains focused on the development of treatment modalities that effectively kill tumor cells without harming normal cells. Thus, novel strategies for targeted cancer therapy are in great demand for effective cancer treatment. [1] The rapid development of multifunctional theranostic materials for biomedical applications show promising potential in cancer therapy. [2] Most of presented in literature nanomaterials can nonspecifically accumulate in cancer tissue through the enhanced permeability and retention (EPR) effect, that is, by passive targeting, albeit with limited dosage and selectivity. [3] Recently, the active, cell-specific targeting of nanomaterials has begun to represent a potentially powerful technology in cancer treatment. Active targeting is achieved by conjugating nanomaterials with targeting ligands that bind to overexpressed antigens or receptors on the target cells. [4]

In our work we would like to propose the construction of several nanosized and regular materials based on selected hydrogel lattices, metallic nanoparticles and covalently and noncovalently introduced oligonucleotide aptamers. We would like to expand the synthesis ways and optimization steps needed for preparation of multicomponent drug delivery system with incorporated DNA and improved delivery properties.

The first way of synthesis involves the application of charge controlled coaxial core-shell electrospinning process for creation of thin micro- and nanocomposites of PLCL/PNIPA/DNA/Au NPs. During electrospinning of polylactide-co -caprolactone (PLCL) polymer and thermoresponsive PNIPA hydrogel composites, selected oligonucleotides and neat and modified Au NPs were introduced into composited. The modification of Au NPs involved covalent and noncovalent attachment of DNA aptamers and selected antitumor drug – doxorubicin. Doxorubicin (Dox) was attached by covalent bonding sensitive to tumor environment, as well, was noncovalently entrapped in DNA structures. We investigated the release profiles of Dox-modified Au NPs from PLCL nanofibers, by spectroscopic (UV-Vis, CD) and electrochemical techniques (CV, SWV) and in vitro experiments (HeLa, Insulinoma and Glioma cells). The morphology of composites was inspected by TEM, SEM and optical microscopy.

Second way assume the introduction of particular conformations of selected aptamers into PAM and PNIPA hydrogel networks, for formation of multicomponent nanoparticles and storing of Dox and releasing of it after initiation of structural changes of aptamers and volume phase transition of lattices. Second kind of lattices was synthesized with Au NPs with attached Dox. The DNA-based biomaterials were characterized by a strong increase in guanine and adenine anodic currents that starts at physiological temperature. [5] The structural alterations were used as a control element in the releasing of doxorubicin. Doxorubicin was slowly released by using a minor temperature increase as it is routinely done in hyperthermia. The binding strength, the rate of release of Dox and the composite properties were examined using voltammetry, SEM and ICP-MS.

# An Ultrasensitive pH-Switchable Electrochemical Immunosensing based on Integrated 3D-KSCs Electrode as Singal Collector and AuNPs-Ab<sub>2</sub>-GOD-ConA as Tracing Tag for Assay of CEA

Jingyi Chen, Yonghai Song, and Li Wang

Key Laboratory of Functional Small Organic Molecule, Ministry of Education, Key Laboratory of Chemical Biology, Jiangxi Province, College of Chemistry and Chemical Engineering, Jiangxi Normal University, Nanchang, 330022, China.

[lwangsy2003@hotmail.com](mailto:lwangsy2003@hotmail.com)

**Abstract:** A novel ultrasensitive immunsensor for detection of the tumor biomarker, carcinoembryonic antigen (CEA), was developed by using AuNPs-Ab<sub>2</sub>-glucose oxidase (GOD)-Concanavalin A (Con A) as pH-switchable immunosensing probe and BSA-Ab<sub>1</sub>/chitosan (CHIT)-AuNPs/integrated three-dimensional macroporous carbon (3D-KSCs) derived from kenaf stem electrode as signal collector based on a sandwich-type assay mode. After a sandwich immunoreaction, the quantitative capture of AuNPs-Ab<sub>2</sub>-GOD-ConA on CEA/BSA-Ab<sub>1</sub>/CHIT-AuNPs/integrated 3D-KSCs electrode could greatly hinder Fe(CN)<sub>6</sub><sup>3-/4-</sup> electron transfer to make cyclic voltammograms response decrease and electrochemical impedance spectroscopy signal greatly increase. The electron transfer hindering of Fe(CN)<sub>6</sub><sup>3-/4-</sup> not only resulted from the increase of modified layer but also the electrostatic repulsion between Fe(CN)<sub>6</sub><sup>3-/4-</sup> and the negatively charged AuNPs-Ab<sub>2</sub>-GOD-ConA. The integrated 3D-KSCs electrode as signal collector not only provided a large specific surface area to load a large number of Ab<sub>1</sub> but also enhanced the mass transfer. As a consequence, the proposed immunsensor could detect CEA with a linear range of 5 pg mL<sup>-1</sup> to 50 ng mL<sup>-1</sup> and a detection limit down to 1.3 pg mL<sup>-1</sup>. In addition, the immunosensor had low cost, satisfactory reproducibility, stability and acceptable reliability. Thus, this method might provide a potential application in clinical diagnostics.

**Scheme 1.** Schematic illustrating of the pH-switchable immunosensor fabrication and sandwich-type immunoassay procedure.

# The GOD/Cu-Hemin Metal Organic Frameworks Nanocomposites for Glucose Sensing

Juan He, Yonghai Song and Li Wang\*

College of Chemistry and Chemical Engineering, Jiangxi Normal University, 99 Ziyang Road, Nanchang 330022, People's Republic of China  
[yhsong@jxnu.edu.cn](mailto:yhsong@jxnu.edu.cn)

**Abstract:** Hemin as a member of iron porphyrin was first used alone as metalloligands to fabricate metal-organic-framework (MOF). In our study, a novel 3D mesoporous metal-metalloporphyrin MOF (Cu-hemin MOF) as peroxidase mimetic has been firstly demonstrated by a simple and facile one-step method in aqueous solution, which has owned a pretty morphology like flower-ball and enjoy a better water-stably. Based on this, glucose oxidase (GOD) has been successfully immobilized into Cu-hemin MOF for glucose detection based on the consumption and reduction reaction of  $O_2$  to obtain a large detection linear range. The GOD/Cu-hemin MOF nanocomposites could be used to achieve glucose detection directly with a wide linear range from 9.10  $\mu M$  to 30.0 mM, and the limit detection has been estimated to be as low as 2.73  $\mu M$ . Moreover, it was also successfully applied to the detection of glucose under coexistence of human serum, which demonstrated a good accuracy for the real samples.

**Scheme 1.** A schematic representation of synthesis and detection mechanism of GOD/Cu-hemin MOF.

In the nervous system, a neuron communicates with another to transmit neural information via synapses. Synaptic transmission for chemical neurotransmitters as well as electrical signals takes place in the synaptic clefts, which are gap junctions between pre- and postsynaptic boutons. The formation and function of synapse involve synaptic cell adhesion molecules (CAMs) localized at the synaptic site. In order to induce synapses between synthetic surfaces and neuronal cells and thereby construct artificial synaptic interfaces, we engineered well-known postsynaptic CAMs, i.e. neuroligin-1 (NL1), neuroligin-2 (NL2), and slitrk-3 (SL3), which were tagged with the fluorescent protein and biotin. The NL1 immobilized on microbead substrates were co-cultured with rat hippocampal neurons, and retained strong preference to the excitatory presynaptic differentiation. In addition, the artificial synapses formed by the NL1 beads maintained regardless of the developmental stages of cultured neuronal cells. While the NL2 and SL3 microbeads induced the strengthened inhibitory presynaptic differentiation when only contacted with the mature neurons. Such artificially induced synapses are reconstituted on the desired positions in the microchannel-guided patterns so that we were able to detect neurotransmitters and electrical signals. The artificial synaptic interface in this work is expected to serve as not only unprecedented electrochemical cell but novel neural interface at which biological nerve cell and electronic circuit exchange information with each other.

# Propagation of the change in the membrane potential -Electrochemical elucidation on nerve conduction-

Osamu Shirai, Yoshinari Takano, Yuki Kitazumi, and Kenji Kano  
Division of Applied Life Sciences, Graduate School of Agriculture, Kyoto University  
Sakyo, Kyoto 606-8502, Japan  
shiraio@kais.kyoto-u.ac.jp

Conduction mechanism of an action potential along a nerve axon was investigated by use of liquid membrane cells. Propagation of the change in a potential difference between two aqueous phases (W1 and W2) across a liquid membrane ( $E_{W1-W2}$ ) was elucidated based on the knowledge of voltammetry for the ion transfer at the interface of two immiscible electrolyte solutions [1,2]. We used a system coupling three liquid membrane cells which were composed of two aqueous phases and a 1,2-dichloroethane solution phase to analyze the change in the membrane potentials of the potential-sending and potential-receiving cells (potential-sending: cells S and Ap, potential-receiving: cell Rec). The ionic composition of the potential-sending cell (S) was identical to that of the receiving cell (Rec), and that of another potential-sending cell (Ap) was different from that of cell Rec. Thus, the membrane potential of cell S or Rec and that of cell Ap mimicked a rest and an action potentials, respectively, observed in the nerve transmission. When the connection of cell Rec was switched from cell S to cell Ap, the change in the membrane potential was caused with the circulating current in the cell system. The properties for the propagation of the change in the membrane potential depend on the ratio of the magnitude of the limiting current at cell Ap versus that at cell Rec. The limiting current observed at the interface, of which the potential difference varies in cell Rec and corresponds to the threshold, and the magnitude of the limiting current at the interface, of which the potential difference varies in cell Ap, reflects the potency of the propagation of the action potential. The potential differences at every interface are controlled by the ion transfers and the circulating current flowed to keep the electroneutrality of every phase.

The influence of some capacitors or some electric resistors on the propagation of the change in the membrane potential was investigated by setting some capacitors or some resistors in the electric circuit [3]. Changing the connection of cell Rec from cell S to cell Ap, the membrane potential of cell Rec varied from the rest potential to a different membrane potential that is close to the action potential. The delay and decrement of the propagation of the change in the membrane potential was observed by setting capacitors or resistors in the electric circuit. It is thought that the change in the membrane potential was reduced by both the potential drop prompted by generation of the circulating current and that the delay of the propagation was caused by the electric charging of the capacitor in analogy with the propagation of the action potential in the nerve transmission.

In order to construct a cell system composed of the cells having the roles of  $K^+$  and  $Na^+$  channels in nerve cells, the cells of which the membrane potentials were determined by the transfer of  $K^+$  and  $Na^+$ , respectively, were prepared. The membrane potential of cell S or Rec at zero current corresponds to the rest potential, and that of cell Ap at the zero current corresponds to the action potential. By coupling multiple Ap cells through the electric relays which begin to work at the membrane potential more than the threshold, the directionality of the propagation of the action potential was investigated. We succeeded in reproducing the propagation of the action potential like the nerve conduction.

# Interaction between Ferric/Ferrous Cytochrome *c* and Cardiolipin: An Electrochemical and Quartz Crystal Microbalance with Dissipation Study

Sin-Cih Sun, Yuan-Hao Hsu, Min-Chieh Chuang

*Department of Chemistry, Tunghai University*

*No. 1727, Sec. 4, Taiwan Blvd., Taichung 40704, Taiwan*

*sandy79325@gmail.com*

Cytochrome *c* (cyt *c*), a protein inherent with a redox-centered heme in ferric/ferrous states, locates in the mitochondrial intermembrane space in eukaryotic cells. The oxidation state of heme regulates structure of cyt *c* and its affinity to electron transport complexes, in which the ferric cyt *c* tends to bind to complex III and the ferrous cyt *c* associates with complex IV. Approximate 15% of the positively charged cyt *c* associates with the mitochondrial cardiolipin (CL) in homeostatic conditions [1] and function as a peroxidase to promote CL oxidation which is referred as an early step towards apoptosis [2]. Although ferric and ferrous cyt *c* have been shown to form complexes with CL, the exact mechanism leading to apoptosis in connection to oxidation state of cyt *c* remains unresolved.

We performed electrochemical techniques to interrogate effect of redox switch (cyt *c*) upon the interaction between cyt *c* and CL. Cyt *c* was functionalized on a carboxylic- and hydroxyl-groups terminated self-assembled monolayer on gold electrode by electrostatic and hydrophobic attraction. Cyclic voltammogram reveals that the formal potentials acquired from both ferric and ferrous cyt *c* shifted to less positive potential (by 19.5 and 15 mV) upon the association with CL. The potential separation of redox waves also increased upon the cyt *c*-CL association. The results correlated with the conclusion obtained in AC voltammetric experiments wherein the ferric cyt *c* exhibited a potential shift (24.1 mV), remarkably greater than 9.2 mV of ferrous cyt *c*, inferring a substantial structural change of ferric cyt *c* upon the association with CL. A molecular modeling also suggested a more perpendicular orientation of heme-plane (in the adsorbed ferrous cyt *c*) to the electrode surface.

The cyt *c*-CL interaction was further interrogated using Quartz Crystal Microbalance with Dissipation monitoring (QCM-D). The mass the ferric cyt *c* adsorbed onto a phosphatidylcholine (PC)/CL (4:1 in molar ratio) lipid bilayer was 2.4-fold greater than the ferrous one which, however, represented greater shear modulus ( $\mu = 1.44 \times 10^3$  Pa) for the binding of cyt *c* to CL. The *D-f* plot revealed different slopes given by ferrous and ferric cyt *c*, presumably ascribed to distinct adsorption kinetics. The ferric cyt *c* displayed two linear regimes with different slopes containing the initial part having a greater slope and the second one giving a slope same with ferrous cyt *c* throughout the adsorption.

# Electrodeposited NiCo bimetallic nanoparticles decorated reduced graphene oxide for highly sensitive and selective determination of dopamine

Yang Liu, Wenyan Zhang

Department of Chemistry, Beijing Key Laboratory for Microanalytical Methods and Instrumentation,  
Tsinghua University, Beijing 100084, P. R. China  
e-mail: liu-yang@mail.tsinghua.edu.cn

Bimetallic nanoparticles, composed of two chemically distinct metals, have aroused extensive interests due to their unique optical, electronic, and especially catalytic properties. The bimetallic-NP-based catalysts often show superior catalytic activity compared with the homologous monometallic counterparts, arising from the synergistic effects of both moieties. However, the aggregation and coalescence of the bimetallic nanoparticles generally reduces the catalytic activity and surface area, which limits its application in biosensing. Because of the huge surface area, high conductivity, and rich physical and chemical functionalities, graphene has been proofed to be a remarkable nanosupport to stabilize nanoparticle with high activity. In this work, a uniform reduced graphene oxide thin film was firstly prepared by a electrochemical deposition, and NiCo bimetallic nanoparticles were anchored on reduced graphene oxide (rGO) by a dual potential electrochemical deposition method (NiCo/rGO). Compared to the single component of NiCo or rGO, the NiCo bimetallic nanoparticles were well dispersed. NiCo/rGO composite modified glassy carbon electrode (GCE) exhibits excellent electrocatalytic activity of dopamine (DA) which plays a significant role in human meta-bolic, renal, cardiovascular, central nervous and hormonal systems and was various detection approaches has been developed. Under optimal condition, the electrochemical biosensor displays high sensitivity toward DA detection. A good linear relationship between the current and the concentration of DA was obtained in the range of 1  $\mu\text{M}$  to 100  $\mu\text{M}$  with A detection limit of 50 nM ( $S/N = 3$ ). In addition, the NiCo/rGO based electrochemical sensor showed excellent selectivity toward DA detection in the presence of ascorbic acid (AA), uric acid (UA) and other interference reagents, and was applied for the DA detection of human serum samples. The results demonstrate the developed approach provides a promising strategy to improve the sensitivity and selectivity of electrochemical biosensors in the application of clinical diagnostics.

# Effect of Nanoscale Surface Morphology on Biorecognition Using Localized Surface Plasmon Resonance (LSPR) Spectroscopy

Alexander Vaskevich,<sup>1</sup> Tatyana B. Bendikov,<sup>2</sup> Ortal Bahar,<sup>1</sup> Ludmila Frolov,<sup>1</sup> Israel Rubinstein<sup>1</sup>

Departments of <sup>1</sup>Materials and Interfaces and <sup>2</sup>Chemical Research Support,  
Weizmann Institute of Science, Rehovot 7610001, Israel  
alexander.vaskevich@weizmann.ac.il

The surface nanoscale morphology has been generally recognized as one of the major parameters determining the properties of adsorbed biological molecules, in cases such as organization of ssDNA on Au nanoparticles (NPs) and nanorods (NRs), proteins on silica and gold NPs, the secondary structure of peptides, the structure of protein corona, oligomerization of surface-bound proteins, and NP-cell interaction.

Metal nanostructures supporting excitation of localized surface plasmons present a unique situation encompassing controllable nanoscale morphology which can be varied over a wide range of shapes and curvatures, from several to hundreds of nm, providing sensitivity of the spectral response that can be tuned to the properties of the environment in the vicinity of the nanostructured surface.

High-resolution scanning electron microscopy (HRSEM) imaging of polyelectrolyte multilayers, adsorbed proteins and immobilized oligo-DNA strands shows formation of rather uniform shells on Au nano-islands (Figure 1). Preparation of morphologically stable LSPR transducers based on Au island films with variable average island size provides a convenient platform for studying the influence of the surface curvature on the organization of biomolecules on surfaces presenting a controlled morphology. We explored the possibility of quantifying the morphology-dependent LSPR response for immobilization and interaction of oligonucleotides and immunoassay using a simple core-shell model which allowed quantification of the optical response.<sup>1,2</sup>

Figure 1. HRSEM images of Au nano-island films coated with (A) a polyelectrolyte multilayer, (B) immobilized 8-His BLIP, and (C) immobilized oligo-DNA (43 bases). Samples B and C were stained before imaging.<sup>3</sup>

Studies of immobilization and hybridization of ss oligo-DNA showed the applicability of a core-shell model to the analysis of immobilization of thiolated and amine-terminated ssDNA, as well as hybridization of ss-DNA on LSPR transducers with variable average island diameter (15–32 nm). Comparison of the model and the experimental data showed a near quantitative correspondence using the effective layer thickness as a single fitting parameter.

We found that the activity of rabbit IgG or anti-rabbit IgG adsorbed directly on the Au surface was preserved over the entire range of island sizes. Binding of anti-rabbit IgG to rabbit IgG on the smallest Au islands was suppressed compared to the larger islands, possibly associated with the similarity in size between the small islands and the IgG proteins. The same antigen-antibody system was tested using indirect binding of the recognition IgG layer to the Au surface via covalent attachment to a pre-assembled monolayer of a linker thiol-NHS. We found that binding of anti-rabbit IgG to covalently tethered rabbit IgG receptor layer shows substantially larger optical response compared to the respective changes associated with binding of the first protein layer. This intriguing observation, not seen in the case of directly adsorbed rabbit IgG receptor layer, suggests a greater than 1:1 antigen-antibody binding ratio on the surface.

## Abstract

Dopamine (DA) is a catecholamine neurotransmitter of significant biologic interest, for its demonstration of the treatment of the central nervous system disorders, such as schizophrenia and Parkinson's disease. Hence, accurate and sensitive determination of DA is vitally important in the diagnosis of various mental diseases. In this work, we develop a novel freestanding metallic microrod as working electrode for highly sensitive and selective electrochemical detection of trace DA. The electrode was facilely fabricated via first dealloying of smooth Au-Ag alloy microrod (AMR) into nanoporous Au-Ag alloy microrod (NPAMR) and further modification with electropolymerized molecularly imprinted polymer (MIP). The 3D open and continuous nanoporous structure of the supportless microrod provides large specific surface area and the outer MIP layer imparts recognition ability of DA molecules to the sensor. Therefore, the outstanding determination performance of the as-prepared sensor arises from coupling the amplification feature of NPAMR with the superior selectivity of MIP. Moreover, the fact that the microrod is able to work without the assistance of a commercial electrode simplifies the construction of sensor system and lowers the cost. Influencing factors including dealloying time, pH value and molar ratio of monomer to template molecule during electropolymerization process were optimized. Under the optimal conditions, a linear range from  $2 \times 10^{-13}$  to  $2 \times 10^{-8}$  mol L<sup>-1</sup> for measuring DA was obtained with a detection limit of  $7.63 \times 10^{-14}$  mol L<sup>-1</sup> (S/N=3), which is lower than the data from all the reported DA sensors we can find. In addition, the MIP-modified electrode (MIP/NPAMR) was successfully employed to test DA in biological samples.

**Keywords** Molecularly imprinted polymer; Nanoporous alloy microrod; Electrochemical sensor; Trace measurement

**Fig. 1** (A) SEM image of NPAMR and AMR (Inset). (B) Comparison of two differently modified sensors before and after binding with  $2 \times 10^{-8}$  mol L<sup>-1</sup> DA at a scan rate of 100 mV s<sup>-1</sup> in 0.05 mol L<sup>-1</sup> [Fe(CN)<sub>6</sub>]<sup>3-/4-</sup>. (C) Calibration curve for DA detection correlating reduction peak current shift with DA concentration by using MIP/NPAMR. There are a lot of attentions of wearable electrochemical devices for monitoring vital signs such as concentration of glucose. We previously reported a screen-printed paper-based flexible biofuel cell based on glucose oxidase and bilirubin oxidase with high disposability and biocompatibility<sup>1</sup>. The fabricated biofuel cell (BFC) exhibited a remarkable power output of  $0.12 \text{ mW cm}^{-2}$ .

In the present study, we developed a high-power paper-based glucose biofuel cell array for self-powered wearable health-monitoring devices. The device is expected to be put on a diaper to generate electricity from the glucose contained in urine, and can wirelessly send information such as glucose- and electrolyte-concentrations. Figure 1 shows the schematic illustration of the present biofuel cell array.

Fig. 1 Schematic illustration of a disk-shaped paper-based biofuel array

The maximum power of the present biofuel array was about  $400 \mu\text{W}$ . The device may find application in health-check systems, thereby decreasing the burden of the nursing staff in a nursing home and similar medical care facilities. In this presentation, we introduce the structure and characteristics of the present biofuel cell array in detail.

Enzyme-linked immune-sorbent assay (ELISA) is a traditional clinical analysis. The assay system utilizes a monoclonal antibody, which directs against a distinct antigenic determinant on the intact CA125 molecule and is used for solid phase immobilization. A rabbit anti-CA125 antibody conjugated to horseradish peroxidase (HRP) is in the antibody-enzyme conjugate solution. The test sample is allowed to react simultaneously with the two antibodies, resulting in the CA125 molecules are being sandwiched between the solid phase and enzyme-linked antibodies. The minimum detectable concentration of CA125 in this assay is estimated to be 5 U/ml. According to the previous research, decreasing the detection limit and increasing analytical sensitive are our study goal [1].

In this study, an electrochemical immunosensor established on graphene sheet (GS) has been developed. Graphene sheet is used to immobilize the mediator thionine (TH), secondary anti-CA125 antibody (Ab2), and gold nanoparticles. The resulting nanostructure (GS-TH-AuNPs-Ab2) is able to use as the label for the immunosensor. By immobilizing primary anti-CA125 antibody (Ab1) and cancer antigen 125 (CA125) onto the nanostructure, the working electrode is constructed by coating the nanostructure on the glassy carbon electrode (GCE) [2]. In order to increase the detecting accuracy of ovarian cancer, multiplexed tumor markers (CA125, CA153) on sandwich-format electrochemical immunosensor are also fabricated [3].

Figure 1 shows our result in differential pulse voltammetry (DPV) measurement. Green line represents the solution only with gold nanoparticles (AuNPs) and reveals two typical peaks, indicating the electron transfer in the electrochemical reaction. When coated with graphene (black line), one of the peaks becomes weak and shows that the oxygen functional group might affect the electron transfer. After adding mediator thionine (red line), the peak turns clearly; it proves mediator can make the signal stronger. Finally we added bovine serum albumin (BSA), the peak becomes small (blue line) due to the BSA is covered on the electrode and inhibits the electron transfer.

Figure 1 Normalized DPV curves of ultra-sensitive electrodes

Wearable device is an advanced technology that can be applied in various fields. For example, the wearable sensor can prevent “drink & driving” by sensing alcohol from the human body before initiation of a car’s engine. Sportswear equipped with a wearable sensor can contribute dramatically to progress of sports science. One of the challenging points in wearable device is deposition of electrical-conductive, usually metallic, materials on the textile. In comparison with other metal deposition methods such as sputtering and evaporation, electroless deposition is the most promising technology at the industrial level because of its simple operation and low cost process. Therefore, study on fabrication of fibers coated with metallic materials by electroless deposition has attracted much attention. However, there are still some problems needed to be improved in electroless plating. First, a pretreatment process is usually needed, and the pretreatment process is performed with toxic substance [1]. In this case, the toxic substance raises concerns for practical use of the fibers in clothing. Second, the fibers can be damaged or even lost because the pretreatment is performed with a strong acid. Third, adherence of the metallic coating on the fibers still needs to be improved.

In previous studies, we have proposed a supercritical CO<sub>2</sub> catalyzation (SCC) method with organo Pd complex followed by an electroless plating method with supercritical CO<sub>2</sub> emulsified electrolyte (ELP-SCE) to improve coverage and adherence of Ni on a Kapton® polyimide film [2-4]. Supercritical fluid is any substance at a temperature and pressure above its critical point. Surface tension of supercritical CO<sub>2</sub> is extremely low, and diffusivity is very high. Therefore, it can improve transfer of materials into very fine space. We believe the SCC and ELP-SCE can also be applied in electroless plating of Ni-P on textile to eliminate the concerns of the toxic chemicals used in the pretreatment and improve adhesion of the Ni-P coating on the textile.

The textile used in this study is Nylon 6,6 fiber. No pretreatment was conducted in this study. The catalyzation was either a conventional method with a PdCl<sub>2</sub>/SnCl<sub>2</sub> mixture solution (CONV-cat) or in the SCC with bis (2,4-pentandionato)-palladium. The catalyzation temperature was 353 K, and pressure for the SCC is 15 MPa. After the catalyzation process, either a conventional electroless plating (CONV-ELP) or ELP-SCE was performed. The reaction temperature was 353 K for both of the plating methods, and pressure of 15 MPa was used for the ELP-SCE. Surface of the Ni-P coatings was observed by an optical microscope and a SEM.

The coated Ni-P by the CONV-cat and the CONV-ELP had many pin-holes and did not show outline of the textile but fused into rough structure. This comes from the individual nodule growth of the Ni-P nuclei during the electroless deposition process. Ni-P coating by the SCC and the CONV-ELP showed rough Ni coating on surface of each fiber, and many peered-off parts were observed. On the other hand, uniform Ni coating on the surface of each fiber was obtained by the SCC and the EP-SCE. These results demonstrate that the SCC is effective to impregnate the Pd catalysts into the fibers and the EP-SCE can inhibit the nodule growth of Ni-P. Thus, the method proposed in this study can metallize surface of each fibers in the textile and has potential to give some functions on textiles.

# Electrochemistry-controlled Photo-induced Electron Transfer in Ubiquinone-based Systems

Xiao-Yuan Liu, Yi-Tao Long\*

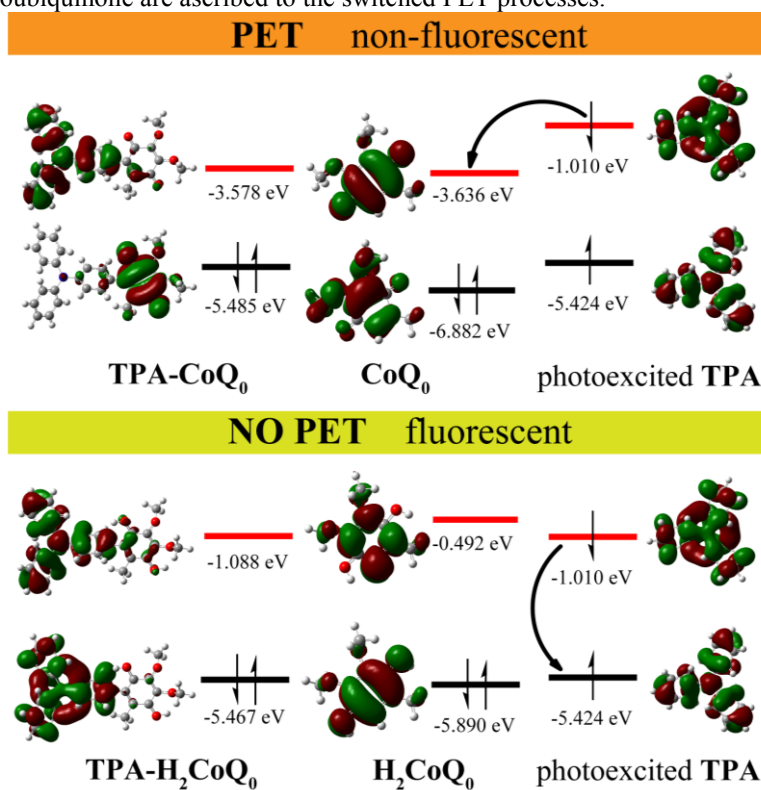

Key Laboratory for Advanced Materials & Department of Chemistry, East China University of Science and Technology, 130 Meilong Road, Shanghai, 200237, P. R. China.

xiaoyuanliu@mail.ecust.edu.cn

In photosynthesis process, photo-induced electron from excited state of  $P_{680}$  in photosystem II (PSII) is transferred along an electron transport chain via three mobile carriers (plastoquinone, plastocyanin and ferredoxin) to fulfill the synthesis process of adenosine triphosphate (ATP) and the reduction of carbon dioxide, where the photo-induced electron transfer (PET) plays an essential role.<sup>1-3</sup>

To research the PET processes, we designed and synthesized a ubiquinone-based triphenylamine compound (TPA-CoQ<sub>0</sub>) to research the PET from optical studies and Density Functional Theory (DFT) calculations. In TPA-CoQ<sub>0</sub>, triphenylamine and ubiquinone acts as electron acceptor, respectively. Ubiquinone undergoes two-step two-electron redox process, which could fine-tune the PET process from triphenylamine moiety to ubiquinone group.

The optical studies indicate the PET process could be fine-tuned via redox processes of ubiquinone and the system exhibits switched “off/on” and “off/on” fluorescent properties between TPA-CoQ<sub>0</sub> and TPA-H<sub>2</sub>CoQ<sub>0</sub>. The DFT calculations demonstrate that the changed LUMO orbitals of ubiquinone/hydroquinone are ascribed to the switched PET processes.

# Defective graphene flake-supported Pd nanocubes as electrochemical glucose sensor

Bang-De Hong, Chien-Liang Lee\*

*Department of Chemical and Materials Engineering, National Kaohsiung University of Applied Sciences  
No. 415, Chien Kung Rd., Kaohsiung 807, Taiwan  
e-mail address: [cl\\_lee@kuas.edu.tw](mailto:cl_lee@kuas.edu.tw); [cl\\_lee@url.com.tw](mailto:cl_lee@url.com.tw)*

Defective graphene flakes (DGFs) is of interesting for the effect in an electrocatalytic process. Previously, we reported a sonoelectrochemical method to rapidly prepared defective grapene flakes (DGF<sub>SECM</sub>) and observed the domination of physical defects on the surfaces of these DGF<sub>SECM</sub> as compared to defective grapene flakes prepared via a chemical reduction method (DGF<sub>CM</sub>) [1]. In this study, the DGF<sub>SECM</sub> and DGF<sub>CM</sub> were used to support these 10 nm Pd nanocubes, forming defective graphene flake-supported Pd nanocubes, successfully used as catalysts for non-enzymatic D-glucose sensor. Compared with the DGF<sub>CM</sub> systems, the DGF<sub>SECM</sub> system has a higher electrochemically real surface area and greater catalytic activity on glucose oxidation. Additionally, there were two linear current-responses relationships for the sensitivities on the DGF<sub>SECM</sub>, DGF<sub>CM</sub> system and DGF-free Pd nanocubes. The DGF<sub>SECM</sub>-supported Pd nanocubes showed the higher sensitivities of  $74 \mu\text{A}\cdot\text{mM}^{-1}\cdot\text{cm}^{-2}$  from 0.25 mM to 5 mM and  $45.86 \mu\text{A}\cdot\text{mM}^{-1}\cdot\text{cm}^{-2}$  from 5 mM to 20 mM. The data in the selective tests depicted that DGF<sub>SECM</sub>-supported Pd nanocubes as compared to DGF-free Pd nanocubes showed remarkable tolerance to foreign ascorbic acid and uric acid, for which DGF<sub>CM</sub>-supported Pd nanocubes had slight current. The low deviation by serum sample analyses further confirmed the potential of DGF<sub>SECM</sub>-supported Pd nanocubes as a glucose sensor.

# Direct detection for ratio of concentrations of HbA1c to total hemoglobin with potentiometric immunoassay

Junko Tanaka, Yu Ishige, and Masao Kamahori

Research & Development Group, Hitachi, Ltd.

1-280, Higashi-koigakubo, Kokubunji-shi, Tokyo, 185-8601 Japan

The increasing number of diabetes patients is resulting in the rise of health care costs. Earlier treatment for patients in the diabetes mellitus preliminary group is considered one of the best ways to suppress the rise of costs in the future. While blood glucose level reflects the severity of diabetes, it is not the best indicator for screening because it fluctuates, even on a daily basis. HbA1c, hemoglobin glycosylated by glucose in the blood, reflects the average blood glucose level for past 1–2 months, so it is considered the gold standard for determining the treatment of diabetes.

Conventionally, HbA1c has been determined by the HPLC method with ion exchange or affinity columns to separate HbA1c from other hemoglobin. Therefore, HbA1c (%), which is the ratio of concentration of HbA1c to total Hb (hemoglobin), is used as the HbA1c indicator. The HPLC method can determine HbA1c (%) directly but requires large and expensive instruments. Antibody-based immunoassay and enzyme-based enzymatic assay methods, which do not require large instruments, are increasingly available to clinical laboratories, but these methods require a separate measurement of total hemoglobin content in the samples and a calculation of the ratio of HbA1c to total Hb. In this study, we developed a potentiometric immunosensor with a direct measurement method for HbA1c (%) measurement to simplify the measurement system.

The developed potentiometric immunosensor is shown in Fig. 1. The target molecules are captured by capture antibodies and a sandwich of the captured antibody-target-labeled antibodies is formed. Alkaline phosphatase as the labeling enzyme hydrolyzes ascorbic acid phosphate (AsA-P) and produces ascorbic acid (AsA). AsA reacts with ferricyanide and produces ferrocyanide. Since redox potential follows the ratio of ferricyanide and ferrocyanide as the Nernst equation, the amount of produced ferrocyanide that is proportional to the amount of captured target can be obtained by measuring the potential of the electrode located nearby. The proposed scheme for HbA1c (%) detection is shown in Fig. 2. Anti-Hb and anti-HbA1c antibodies were used for capture and labeled antibodies, respectively. The capture antibodies capture a certain portion of Hb maintaining HbA1c (%) in the sample blood. The enzyme-labeled antibodies detect only HbA1c in captured Hb. As a result, the HbA1c (%) can be directly measured without Hb measurement. The results of HbA1c (%) measurement using our developed potentiometric immunosensor showed good correlation between certified and experimental values of HbA1c (%) (Fig. 3).

Fig. 1 Potentiometric immunosensor.

Fig. 2 Proposed scheme for HbA1c% detection.

Fig. 3 Experimental results.

# Electrospun, conductive polymer fleeces as electrode materials for enhanced bioelectrocatalysis

J. Gladisch<sup>1</sup>, D. Sarauli<sup>1</sup>, B. Schulz<sup>2</sup>, F. Lisdat<sup>1</sup>

*1- Biosystems Technology, Institute of Applied Life Sciences, Technical University Wildau, Germany,*

*e-mail: flisdat@th-wildau.de*

Polyanillines as conductive polymers have found widespread applications in the area of biosensors. By sulfonation of the polymers properties such as solubility and conductivity at neutral pH values can be significantly improved [1]. It is already known that by combining sulfonated polyanillines with PQQ-dependent glucose dehydrogenase (PQQ-GDH) efficient enzyme electrodes with direct electron transfer can be prepared [2,3].

In electrochemical sensors the surface and the surface area are critical parameters influencing strongly the overall performance. Several techniques and materials have been applied in the last couple of years in order to enhance the surface area available for fixation of the biocomponent and signal generation. A rather young technique for this field of application is the electrospinning process. Here polymeric fleeces with rather thin polymer fibers down to about 100nm can be prepared.

In this study the electrospinning technique was intended to be combined with the conductive properties of sulfonated polyanillines and to exploit the potential of direct electron transfer from the substrate reduced enzyme PQQ-GDH to polyaniline. In order to spin the polymer into fibers the sulfonated polyaniline was mixed with polyacrylonitrile. In this mixture different sulfonated polyanillines have been tested. Conditions can be found in order to obtain a homogeneous coverage of ITO electrodes. Within the polymer fleeces a sufficient conductivity can be ensured by the polyaniline polymers used. PQQ-GDH can thus not only be immobilized on the polymeric fiber network, but can also be connected with the electrode. In the presence of the enzyme substrate consequently a catalytic current was obtained. The efficiency was found to depend on the substitution pattern on the polyaniline chain used. For the best system bioelectrocatalysis started near the redox potential of the enzymes redox center.

With this study it could be shown that bioelectrocatalysis with electrospun matrices is feasible.

# Measurement of oxygen consumption of contracting C2C12 myotube using scanning electrochemical microscopy

Yuki Igaki, Fumio Mizutani, and Tomoyuki Yasukawa  
Graduate School of Material Science, University of Hyogo  
3-2-1 Koto Kamigori Ako Hyogo 678-1297, Japan  
Ri14p002@stkt.u-hyogo.ac.jp

## 1. Introduction

C2C12 myoblast is a mouse skeletal muscle cell line with a differentiation potential to myotube with a contraction property, which have been used to investigate skeletal muscle physiology and functions of muscle. Oxygen consumption which reflects the respiration activity of cells is useful as an indicator for the cellular metabolism. Scanning electrochemical microscopy (SECM) has been used to investigate the respiration and metabolic activities of individual living cells. SECM measurement allows to the non-invasive determination of oxygen and imaging of oxygen distribution in the vicinity of a targeted cell. In this study, the reduction currents of oxygen were monitored by Pt microelectrode tip positioned close above an inspected myotube to detect an oxygen consumption of contractile myotubes.

## 2. Material and method

C2C12 myoblasts were cultured on a dish (60 mm diameter) treated with collagen in a growth medium of Dubecco's modified Eagle's medium (DMEM) containing 10% fetal bovine serum at 37°C, under a 5% CO<sub>2</sub>. Myoblasts were then cultured in DMEM containing 2% horse serum and 1 nM insulin for inducing the differentiation into myotubes. An electric pulse stimulation were applied to myotubes appeared four days after changing medium by using cover of cell culture dish with Au wire electrodes (1.0 mm diameter, 40 mm distance). The contraction was induced by applying electric pulses with the voltage of 0.7 Vmm<sup>-1</sup>, the frequency of 1.0 Hz with the pulse duration time of 2.0 ms by using the Au electrodes for 2.5 h. The microelectrode was positioned at 50 µm away from a dish surface in 25.0 mM HEPES buffer containing 5.0 mM KCl, 1.8 mM CaCl<sub>2</sub>, and 140 mM NaCl adjusted at pH7.6 by NaOH. The average height of the differentiated myotubes was 40 µm. The potential of -0.4 V was applied to the microelectrode to detect the reduction current of oxygen.

## 3. Results and discussion

After electric pulses were applied for 2.5 h, myotubes contracted immediately after the electric pulse was applied and returned to its original shape within 200 ms. The beating of myotubes was synchronized with the periodic pulses from 0.017 Hz (1 min<sup>-1</sup>) to 5.0 Hz, while no beating was observed by applying electric pulses beyond 5.0 Hz. Figure 1 show the current responses for oxygen at Pt microelectrode that was placed 10 µm above the myotube (300 µm length, 30 µm width) upon electric pulses by Au wire electrodes. when the electric pulses with 1.0 Hz were applied to induce the contraction of the myotube for 2 min, the reduction current immediately decreased and reached an almost steady-state in 30 s, indicating that the concentration of oxygen around the myotube decreased due to the consumption of oxygen by the increase of the respiration activity. The reduction current returned to its original level within approximately 30 s, when the application of pulses was turned off. When the electric pulses with 0.5 Hz were applied for 2 min, the reduction current also decreased to reach a steady-state. However, the decrease of the reduction current by applying electric pulses with 0.5 Hz is half that with 1.0 Hz. These results indicate that the increase of the oxygen consumption by the respiration of single myotubes per single pulse would be constant.

Fig.1. Current responses of oxygen upon electric pulses by Au wire electrodes. Frequencies of applied pulse were set at (A) 1 Hz and (B) 0.5 Hz. Therefore, microelectrochemistry based on the SECM can be applied to monitor the oxygen consumption of contractile myotubes

# Characterization of Glucose Oxidase-Redox Hydrogel on MgO-templated Carbon Electrode

Aimi Suzuki, Kazuki Murata, Seiya Tsujimura\*,

Division of Materials Science, Faculty of Pure and Applied Sciences, University of Tsukuba

1-1-1 Tennodai, Tsukuba, Ibaraki 305-8573, Japan

seiya@ims.tsukuba.ac.jp

A redox hydrogel electrode in which enzymes are wired with an Os-complex water-soluble redox polymer with a crosslinker on the electrode allows for glucose electrooxidation current densities on flat glassy carbon (GC) electrodes as high as a few milliamperes per centimeter squared at 37 °C. In most cases, electron transfer within the hydrogel film would be the rate-limiting step. To overcome this issue, one approach is introducing a porous carbon scaffold to form an ultrathin hydrogel film and reduce the electron transfer distance. Our group developed a pore-size-controlled carbon material, MgO-templated carbon (MgOC) [1], as a hydrogel scaffold. The hydrogel-coated MgOC (38-nm-diameter mesopores)-modified electrode with deglycosylated flavin adenine dinucleotide-dependent glucose dehydrogenase exhibited greater than 200 mA cm<sup>-2</sup> at 37 °C and a hydrogel loading of 1600 µg cm<sup>-2</sup> [2]. The design of a hierarchical electrode structure would be a very promising approach for the development of hydrogel electrodes for the applications of continuous blood-sugar-level monitoring and biofuel cells.

On the basis of the hierarchical structure-controlled MgOC electrode, we used Glucose Oxidase (GOx from *Aspergillus niger*), which is commercially available and the most widely used enzyme, as an electrocatalyst to produce a high and stable glucose oxidation current. The MgOC used in this study was kindly provided by Toyo Tanso (CNobel®, Japan) with an average pore diameter of 38 nm and a narrow pore-size distribution. The MgOC was modified on a glassy carbon disk electrode (GC-E, 3-mm diameter, BAS, Japan) by electrophoretic deposition (EPD) as follows: MgOC particles were electrodeposited on GC-E by applying a DC voltage at 50 V between these two carbon substrates for 60 s in acetonitrile containing MgOC and poly (vinylidene difluoride). The electrode was dried in air at room temperature. A biocatalyst solution including GOx, poly (1-vinylimidazole) complexed with [Os(bipyridine)<sub>2</sub>Cl] (PVI-Os), and poly (ethylene glycol) diglycidyl ether, was placed by a syringe onto the MgOC-modified electrode (MgOC-E), which was made hydrophilic by plasma oxidation before modifying the hydrogel. PVI-Os was synthesized and partially quaternized to improve water solubility. After modifying the hydrogel, the electrode was dried at 4 °C for 18 h.

Figure 1 shows the cyclic voltammograms for the hydrogel electrode using the MgOC and GC electrodes in the presence of 500 mM of glucose with a total hydrogel loading of 800 µg cm<sup>-2</sup> at 37 °C. The glucose oxidation current for the MgOC-hydrogel electrode was 63 ± 2 mA cm<sup>-2</sup>, which was 13 times higher than that for the GC-E. To the best of our knowledge, this is the first time that such high current densities are reported using GOx as an electrocatalyst. The steady-state current of the MgOC-E reached 0.85 V, which would be due to the solution resistance at a high current.

We will also represent a dependence of the glucose oxidation current on the hydrogel loading, and stabilities of the continuous current responses of the hydrogel electrodes on the MgOC-E, compared to that on the GC-E.

Figure 1. Cyclic voltammograms for glucose oxidation on the MgOC-E (solid curve) and GC-E (dotted curve); total hydrogel loading of 800 µg cm<sup>-2</sup>, 500 mM of glucose, 100 mM of phosphate buffer, pH 7.0, 37 °C, 8000 rpm, 20 mV s<sup>-1</sup>.

# New enzymes for the hybrid enzymatic and organic electrocatalytic cascade for the complete oxidation of glycerol

Sofiène Abdellaoui<sup>a</sup>, David P. Hickey<sup>a</sup>, Matthew S. McCamant<sup>a</sup>, Matthew S. Sigman<sup>a</sup> and Shelley D. Minteer<sup>a</sup> <sup>a</sup>Department of Chemistry, University of Utah, 315 S 1400 E, Salt Lake City, Utah, 84112, USA.  
Sofiène.abdellaoui@gmail.com

The complete electrochemical oxidation of the biofuel, glycerol, to CO<sub>2</sub> using a hybrid enzymatic and organic catalytic system has been demonstrated<sup>1</sup>. This system combines an organic catalyst, 4-amino-(2,2,6,6-Tetramethylpiperidin-1-yl)oxy (TEMPO-NH<sub>2</sub>) with oxalate oxidase (OxOx), resulting in the complete electrochemical oxidation of glycerol at a carbon electrode (Figure 1). This hybrid approach consists of five initial oxidative steps (by TEMPO), resulting in the oxidation of glycerol to mesoxalic acid (**1** → **6**, Figure 1). A combination of OxOx and TEMPO then facilitates the oxidation of mesoxalic (**6**) acid to glyoxalic acid (**7**), oxalic acid (**8**), and finally, CO<sub>2</sub>.

Nevertheless, this system is partly limited, by the weak overlap in pH profiles of OxOx and TEMPO, the first working at acidic pH (pH 4.0) and the latter preferring alkaline pH. Moreover, the electrons generated in the cascade reaction by enzymatic oxidative steps are not mediated to the electrode (4 / 16 electrons) and the OxOx substrate range is limited.

In order to improve this system, we are investigating new enzymes to replace OxOx. Like this latter, Oxalate decarboxylase (Oxdc) belongs to the cupin superfamily of proteins and incorporates mononuclear manganese ions coordinated by four amino acids<sup>2,3</sup>. This enzyme is able to transform oxalate to formate and CO<sub>2</sub>, with O<sub>2</sub> acting as a unique cofactor which can be used to catalyze a side oxidation reaction with o-phenylenediamine<sup>4</sup> or 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) (ABTS). Therefore, efforts have been focused on screening redox mediators which could be coupled with this enzyme. Otherwise, preliminary results with the OxOx of *Bacillus subtilis* expressed in *E. coli* have shown that this enzyme has a residual activity with other substrates, such as mesoxalic acid and glyoxalic acid. The direct evolution of Oxdc could be performed to yield new enzymes with improved activity, broader substrate range and pH range.

**Figure 1:** Electrocatalytic Oxidation Cascade of Glycerol by TEMPO and Oxalate Oxidase<sup>1</sup>

*ausra.baradoke@ftmc.lt*

Electrochemical detection of biomarkers is a promising strategy for the next generation of diagnostic methods and instrumentation [1]. Graphene is a rather new material which is widely used for many application, including electroanalysis. Graphene electrodes modified with specific antibodies for target protein have been already demonstrated and they are in particular interesting as low-cost, disposable biosensors for point-of-care applications [2].

Nevertheless, preparation of graphene modified electrodes is a challenging task due to aggregation of graphene flakes [3]. Therefore, we have been developing graphene oxide modified electrodes on different supports and currently we are focusing on functional fabrication of such electrodes [4]. We have employed the thin film processes and prepared electrodes by the spin-coating technique from graphene oxide suspensions in aqueous chitosan solutions. We analyzed in detail the resulting electrode morphology by applying optical and atomic force microscopy.

Also, we demonstrated that an inkjet printing system can be used for stable immobilization of capture antibodies on the electrode surface, which, in turn, could be pre-structured by other microfabrication techniques. We have investigated the electrode characteristics by means of electrochemical measurements, including cyclic and square wave voltammetries as well as electrochemical impedance spectroscopy, and we discuss these results in comparison with other similar electrode systems.

# Glucose Biosensor based on a Glassy Carbon Electrode Modified with Poly(methylene green) and FAD-dependent Glucose Dehydrogenase

Nozomu Tsuruoka, Kazuki Murata, Seiya Tsujimura,  
Division of Material Science, Faculty of Pure and Applied Sciences, University of Tsukuba  
1-1-1 Tennodai, Tsukuba, Ibaraki 305-8573, Japan,  
seiya@ims.tsukuba.ac.jp

## [Introduction]

Enzyme modified electrodes for electrochemical glucose-oxidation have been used to improve the QOL of diabetic people with less pain, complications, and anxiety. Recently increasing number of glucose sensors utilize flavin adenine dinucleotide (FAD) dependent glucose dehydrogenase (FAD-GDH)[1] as a catalyst which requires appropriate redox mediator to assist electron transfer from the enzyme to electrode. The majority of personal blood glucose sensors are based on disposable enzyme electrode test strip using diffusional mediator such as ferricyanide or ferrocene. Meanwhile, continuous glucose monitoring (CGM) system gathers increasing attentions to get a more complete picture of the glucose levels, which can lead to better glucose control. For the construction of CGM system, it is essential to jointly immobilize the enzyme and mediator on an electrode surface for a long period. Redox hydrogel technology using osmium redox polymer pioneered by Heller [2] allows a fast electron exchange and stable sensor response; however, it has a drawback in cost. To develop an immobilized redox mediator, we focused on methylene green, which can be electropolymerized by potential cycling on glassy carbon electrode [3]. In this paper, we exploit an electropolymerized methylene green as a redox mediator for FAD-GDH.

## [Experimental]

Methylene green (MG) was polymerized electrochemically onto a glassy carbon (GC) electrode, 3mm in diameter, by cycling the applied potential between  $-0.4$  and  $1.2$  V vs. Ag|AgCl at scan rate  $50$  mV/sec for  $10\sim30$  cycles in a  $100$  mM, pH  $7$  phosphate buffer solution containing  $100$  mM  $\text{NaNO}_3$  and  $1$  mM MG.  $0.5$   $\mu\text{L}$  aliquot of  $4.5$  mM FAD-GDH solution was dropped onto the poly(methylene green) (PMG)-modified GC electrode. The solvent was allowed to evaporate and then the surface was covered with a dialysis membrane. The glucose oxidation current by FAD-GDH on PMG-modified GC was measured with stirring in a  $100$  mM phosphate buffer by chronoamperometry at  $0.5$  V. All experiment was carried out in an oxygen-free solution, platinum wire were used as the counter electrode.

## [Results and Discussion]

Dotted line in Figure 1 (1) shows cyclic voltammogram (CV) of PMG-modified on GC electrode in the absence of FAD-GDH, which shows PMG was successfully modified on GC [3]. Solid line shows the catalytic CV for glucose oxidation by FAD-GDH. This result indicates PMG modified on GC worked as a redox mediator for FAD-GDH. Figure 1 (2) shows the typical time dependence of the catalytic current on successive addition of  $0.2$  mM glucose to a neutral buffer solution. The catalytic current reached its limiting value within  $60$  sec and increased with successive glucose injection. The response is liner over the investigated range from  $0$  to  $1.0$  mM glucose.

Using ferricyanide ( $\text{Fe}(\text{CN})_6^{-3}$ ) as a mediator for glucose oxidase (GOx) to catalyze glucose is the most popular strategy in the development of blood-glucose biosensor. Generally, increase of  $\text{Fe}(\text{CN})_6^{-3}$  concentration can improve the catalytic rate of GOx for glucose, but over-added  $\text{Fe}(\text{CN})_6^{-3}$  may affect the micro environment around GOx, resulting in the deactivation of GOx with a short lifetime. In the study, poly-L-lysine (PLL) was used as polycations to entrap and counterbalance the negatively charged GOx and  $\text{Fe}(\text{CN})_6^{-3}$  on NaOH-preanodized screen printed carbon electrodes (named  $\text{SPCE}_{\text{NaOH}}$ ). The effect of the ratio of poly-L-lysine/GOx/ $\text{Fe}(\text{CN})_6^{-3}$  composite on the calibration curves of glucose sensors was showed in Fig. 1. The ratio of GOD: $\text{Fe}(\text{CN})_6^{-3}$  (0.5 mM:9.5 mM) entrapped by 5 mM PLL presented the larger sensitivity and catalytic rate, as shown in the Fig. 1(a). Moreover, the sensitivity, the linear range and the catalytic rate increased with the number of coating layer. Furthermore, the sensitivity can be promoted with the increase of PLL concentration (Fig. 1(b)). When the concentration of PLL and  $\text{Fe}(\text{CN})_6^{-3}$  simultaneously increased to 50 mM and 99.5 mM, the sensitivity of biosensors was as high as  $132.83 \pm 13.63 \text{ nA/mM mm}^2$ . The results indicate that the optimal ratio of PLL/ $\text{Fe}(\text{CN})_6^{-3}$ /GOD composite permits the glucose biosensors to exhibit the better catalytic rate of GOD and sensitivity.

**Fig. 1** Chronoamperometry of  $\text{SPCE}_{\text{NaOH}}$  coated by 5 mM PLL and the three kind of GOD: $\text{Fe}(\text{CN})_6^{-3}$  ratio (0.25 mM:9.75 mM, 0.5 mM:9.5 mM, 1 mM:9 mM) (a) and coated by the composite of 0.5 mM GOx, 9.5 mM  $\text{Fe}(\text{CN})_6^{-3}$  and three kind of PLL concentration (5, 25, 50 mM) (b). The inset shows the corresponding calibration curves.

[sydeng@njust.edu.cn](mailto:sydeng@njust.edu.cn), [danshan@njust.edu.cn](mailto:danshan@njust.edu.cn)

Early growth response protein 1 (EGR1), as a characteristic example of zinc finger proteins, acts as a transcription factor in eukaryotic cells, mediating protein-protein interactions. Here, a novel electrochemiluminescence (ECL)-based protocol for EGR1 assay was developed with a new eco-friendly emitter: nanoclay-supported zinc *proto*-porphyrin IX (ZnPPIX) (**Scheme 1**). It stimulates an intense monochromic ECL irradiation at 644 nm in the aqueous solution with the dissolved oxygen as an endogenous coreactant. This ECL derivation was rationalized via hyphenated spectroscopy and theoretical calculation. To promote hydrophilicity and solid-state immobilization of porphyrins, the lamellar artificial laponite was employed as a nanocarrier owing to its large specific area without the black-body effect. The facile exfoliation of laponite produced quality monolayered nanosheets and facilitated the adsorption and flattening of PPIX upon the surface, resulting in a highly efficient ECL emission. Based on the release of  $\text{Zn}^{2+}$  in zinc finger domains of EGR1 upon contact with the ECL-inactive PPIX, which was monitored by circular dichroism and UV-absorption, a sensitive  $\text{Zn}^{2+}$ -selective electrode for the "signal-on" detection of EGR1 was prepared with a detection limit down to  $0.48 \text{ pg mL}^{-1}$  and a linearity over 6 orders of magnitude. The proposed porphyrin-based ECL system thus infused fresh blood into the traditional family of ECL nanoemitters, showing great promise in bioassays of structural Zn(II) proteins and zinc finger-binding nucleotides.

**Scheme 1.** Schematic illustration of a typical protocol for the ECL assay of zinc finger proteins.

# Application of Polyfolates to the Development of Enzymatic Biosensors

Raimonda Celiešiūtė, Aneta Radzevič, Tomas Rakickas, Živilė Ruželė, Šarūnas Vaitekoniš,  
Tautvydas Venckus, Rasa Pauliukaite

Enzymatic electrochemical biosensors are fast and selective tool for analyte analysis. However, their sensitivity and stability is still problematic and require improvements. In order to extend the lifetime of an enzymatic electrochemical biosensor, natural materials as mediators are preferred to be used in the development of these biosensors.

Recently, it has been shown that some vitamins, in particular, folic acid (vitamin B<sub>9</sub>) can be polymerized and used as redox mediator as well as conducting polymer in electrochemical biosensing [1,2]. The polymerization efficiency of folic acid depends significantly on solution pH and supporting electrolyte. It has been found that Cl<sup>-</sup> accelerates polymerization of vitamin B<sub>9</sub> [1,2]. The most stable electrochemically grown polymer was obtained when it is deposited from pH 2.0 [1]. However, such biosensor showed a poor sensitivity. The sensitivity of the biosensor has been increased when polyfolate was electrosynthesized from phosphate buffer saline solution, pH 5.0 [2]. In order to increase its stability, the polyfolate has been covered with graphene-chitosan composite layer, which was optimized previously [3].

Fig. 1. Scheme of a biosensor design

The similar strategy was applied to the development of other enzymatic biosensors based on oxidases (Fig. 1). This approach has been attempted with such enzymes as glucose oxidase, xanthine oxidase, alcohol oxidase, glutamate oxidase and cholesterol oxidase. All these biosensors were successfully developed using the same design, however, their analytical parameters and stability differ significantly; this will be discussed in the presentation.

# Biosensors with Electrochemical Detection at High Negative Potentials in Flow Systems

Bohdan Josypčuk, Oksana Josypčuk

*J. Heyrovsky Institute of Physical Chemistry of AS CR, v.v.i.*

*Department of Biomimetic Electrochemistry*

*Doležskova 2155, 182 23 Prague, Czech Republic*

High selectivity and sensitivity are great advantages of biosensors with electrochemical detection. Electrochemical detection in flow analysis is widely used especially in connection with biosensors. Detection (working) electrode is the basic element and the sole source of analytical signal in electrochemical methods. Depending on properties of the analyte and on conditions of measurements a suitable electrode material must be chosen. Electrodes of gold, platinum or of other, mostly noble metals, are used for work in positive potential range and for analyte oxidation. Electrodes of various types of carbon are suitable for measurements not only at positive potentials, but also at moderately negative ones. The best possibilities for performing electroreduction processes, particularly at high negative potentials, provide mercury and amalgam electrodes. High hydrogen overvoltage on these materials allows to work in aqueous solutions up to  $-2$  V.

Incorporation of pure mercury electrodes in flow systems and especially for biosensors preparation is complicated due to mechanical instability of the mercury drop, and therefore the Hg-electrodes are practically not used for this purpose. Construction of solid and paste amalgam electrodes is not different from electrodes of other materials suitable for flow analysis [1]. The very useful advantage of solid amalgams is the possibility to prepare electrodes of required size and shape. The silver solid amalgam (AgSA) detectors were used for work in wall-jet and thin-layer arrangement of an electrolytic cell. Introduction of tubular AgSA-detector substantially simplified the design of flow electrochemical cell and increased the reliability and reproducibility of measurements [2].

Sensitivity of the enzyme biosensors depends on the area covered by the enzyme. Classical solid detection electrodes have a relatively small surface which can be enlarged by use of an enzymatic reactor. The large surface of the enzymatic reactor can be provided by various porous or powdered materials. The reactor is placed in flow system in front of the detector. In this case, the biosensor consists of two separate parts: the enzymatic reaction takes place in the reactor and the detector then registers either some product of enzymatic reaction or, e.g., decrease/increase of oxygen concentration in the solution [3]. Recently, we have prepared silver solid amalgam as a suitable porous material and we have used this material for preparation of the enzymatic reactor with a large surface [3]. The flow biosensors based on the minireactor filled by powdered silver solid amalgam covered by enzyme were constructed and tested for the first time [4]. Enzymes ascorbate oxidase, glucose oxidase, sarcosine oxidase, catalase, tyrosinase and laccase were used to test the biosensors. Reactor with enzyme modified porous amalgam or amalgam powder can be substituted in a few seconds by reactor with other enzyme, and it is possible to immediately start measurement of an appropriate analyte. The fabricated silver amalgam tubular detector in a flow system allowed the use of highly negative potentials, which significantly increased the current response and consequently the sensitivity of the determinations. Using high negative potential allows to measure such compounds reduction of which on other electrodes is not possible. The suggested procedure for preparing the biosensors is universal and suitable for covalent attachment of various substances containing  $-NH_2$  group to the amalgam surface.

ardandra@ffclrp.usp.br*

We prepared and characterized biocathodes for a methanol/O<sub>2</sub> biofuel cell using the crude extract and a purified laccase from a strain of *Pycnoporus sanguineus* (PyS). The biocathode assembly was achieved by immobilizing either the enzymes in the crude extract or the purified laccase with polyamidoamine (PAMAM) dendrimers on top of a polypyrrole matrix containing entrapped 2,2'-azino-bis{3-ethylbenzothiazoline-6-sulfonate} (ABTS) species as the redox mediator. The kinetic characterization of the biocathodes showed that samples prepared with either the crude extract or the purified laccase retained ABTS oxidation activity after the immobilization procedure. The electrochemical activity of the biocathodes was verified by cyclic voltammetry experiments in the absence and in the presence of dissolved oxygen. The biofuel cell tests showed that the biocathodes were able to furnish maximum power densities of 51.2 and 99.8  $\mu\text{W cm}^{-2}$  for the samples prepared with the crude extract and the purified enzyme, respectively. Moreover, it was observed that both biocathodes tested displayed a very similar loss in power performance as a function of time, reaching 60% of the initial activity after 60 days. Overall, the laccase-based biocathodes prepared are able to achieve high electrochemical active and stable biomaterials.

Polarization and power density curves: (▲) crude extract (●)purified laccase from PyS, in acetate buffer pH 4.5, containing 0.1 mol L<sup>-1</sup> methanol.

# Scanning Electrochemical Microscopy of Switchable Redox Enzyme Cascades

Christian Andre Gunawan, Ekaterina Nam, Pall Thordarson, Chuan Zhao  
*School of Chemistry, The University of New South Wales  
Kensington Campus, Sydney, New South Wales, 2052  
christian.gunawan@unsw.edu.au*

In the past decades there have been substantial efforts devoted to the development of method to control activity of redox proteins and enzymes. However, most proposed systems suffer from one major shortcoming.<sup>1-3</sup> That is, once the enzymatic cascade has been initiated after introducing all the necessary substrates, it is difficult to control and study the catalytic activity of individual enzymes, and it is almost impossible to modulate or switch off the cascade.<sup>4,5</sup>

We are developing a novel strategy for temporal and spatial control of redox enzymes cascade by either photochemical and/or electrochemical stimuli. This will be achieved by utilizing metallo-bisterpyridine (M(X)tpy<sub>2</sub>) as redox-active chromophores. This chromophore can be excited at specific wavelength and/or redox potential. The chromophore is bioconjugated to redox active protein or enzymes, which will enable them to function as a switch to control the redox activity.

This presentations concern several aspects of the cascade construct including, surface modification by using self-assembled monolayers (SAMs). Organothiols on gold or organosilane/organophosphonic acid on glass, coupled with soft lithography to achieve microscale patterns with high fidelity. Click chemistry of the ruthenium(II)bis(terpyridine) bioconjugate, followed by reconstitution of the cytochrome *c* redox co-factor and cytochrome *c* peroxidase on the surface. Scanning electrochemical microscopy will then be employed to analyze the activity of the surface-bound cascade with and without the external photo/electrochemical stimuli.

# Amperometric bromide biosensor based on graphite powder composite electrode modified with leaf paste of natural *amaranth* induced by spaying KBr aqueous solution

Yongchun Zhu, Jie Hao, Jianqiao Lang, NanXiao, Amin Bao,  
Institute of energy and environment catalysis, Shenyang Normal University  
253 Huanghe street Huanggu District Shenyang Liaoning China  
e-mail Yongchunzhu@126.com

According to biochemical reaction of enzyme or other biological units and targets we build up biosensors[1]. Can we build up a biological unit for a given target? The answer is yes. Here we present an example to show creating biunit for bromide biosensor by target-inducing plant secretion. As we known amaranthine existing abundantly in *amaranth* plants is an antioxidant, and can be used in catalytic spectrophotometric detection of bromide[2]. But natural *amaranth* leaf is not suitable to build up a tissue paste biosensor [3]. In this work, natural *amaranth* plants were schematically treated by spaying lower concentration of potassium bromide aqueous solution to induce the secretory compound for bromide detection. After the induction process, the *amaranth* leaf paste was used to build up a plant paste modified graphite powder composite electrode.

Fig.1 shows the induced *amaranth* paste modified electrode gives a unique electrochemical oxidation behavior in differential pulse voltammetric curve (A1), but the uninduced plant leaf paste modified electrode gives a broadened oxidation peak with lower oxidation peak potentials(A3), while the nearby plant paste modified electrode gives a similar peak with smaller peak current as induced one(A2). Under the suitable experimental conditions, the oxidation current was inverse to the logarithm of bromide concentration in the range of  $1.0 \times 10^{-16} \sim 1.0 \times 10^{-9}$  M with two lines and the minimum detection limit of  $1.0 \times 10^{-16}$  M. The biosensor was applied in the detection of bromide in fresh seaweed with reasonable results. The idea can be used to build up other target biosensors from various biosystems to create some suitable biounits.

Fig.1 DPV curves of *amaranth* leaf paste modified electrodes (A) and working curve for bromide detection. 1, leaf from an *amaranth* induced by bromide; 2, from the nearby plant; 3, from the plant without induced.

# Electrochemical Study of the Extracellular Electron Transfer of *Enterococcus faecalis* to Electrodes

Galina Pankratova<sup>a</sup>, Kamrul Hasan<sup>a</sup>, Donal Leech<sup>b</sup>, Lars Hederstedt<sup>a</sup>, and  
Lo Gorton<sup>a</sup>

<sup>a</sup>*Lund University, Lund, Sweden*

<sup>b</sup>*National University of Ireland Galway, Galway, Ireland*  
*galina.pankratova@biochemistry.lu.se*

*Enterococcus faecalis* is a gram positive bacterium, being a part of the natural microflora that inhabits the gastrointestinal tracts of mammals. It grows by fermentation with lactic acid as the main end product and can use more than 30 carbohydrates as substrates. This bacterium is a facultative anaerobe and aerobic respiration depends on the presence of heme, which serves as a cofactor for cytoplasmic catalase [1] and membrane bound cytochrome *bd* oxidase [2]. *Enterococcus faecalis* does not require heme to grow and lacks the genes to synthesize it but is able to take up heme or its analogues from the environment. When the cells are supplied with heme, an oxygen minimal respiratory chain is built up, including several NADH dehydrogenases, a demethylmenaquinol pool in the membrane and the heme-dependent cytochrome *bd* oxidase [3]. The bacterial cells were “wired” with an osmium containing redox polymer to facilitate electron transfer from the cells to the electrode in the presence of a substrate [4].

The aim of this study was to investigate the role of each of the respiratory chain components and according to this to find out the mechanism of the extracellular electron transfer from the bacterial cells and the redox polymer modified electrode.

In this connection the wild type as well as three different strains of *Enterococcus faecalis* with different mutations within the electron transport chain were investigated using cyclic voltammetry and chronoamperometry under flow injection conditions and different experimental and culture conditions to find out possible ways which the electrons follow from the cell to the electrode.

This work was financially supported by the European Commission (project “BIOENERGY” FP7-PEOPLE-2013-ITN-607793) and the Swedish Research Council (project 2014-5908).

# Label-Free Biomimetic Electrocatalysis-Induced Precipitation for Ultrasensitive Bioanalysis

Peixin Yuan, Shengyuan Deng, Xubo Ji, Peng Xin, Dan Shan\*

School of Environmental and Biological Engineering, Nanjing University of Science and Technology

No.200 Xiaolingwei, Xuanwu District, Nanjing 210094, P.R. China

[sydeng@njust.edu.cn](mailto:sydeng@njust.edu.cn), [danshan@njust.edu.cn](mailto:danshan@njust.edu.cn)

The pursuit of more specific and sensitive signals is a perpetual goal for modern biosensors. Here we proposed a novel label-free strategy of biomimetic electrocatalysis-induced precipitation (BEP) based on the electrochemistry-coupled surface plasmon resonance (*e*-SPR) technique for ultrasensitive detection of DNA (Scheme 1). The protocol starts with the modification of gold disk with peptide nucleic acid as capture probe (*c*DNA). After the association of immobilized *c*DNA with target DNA (*t*DNA), the hybridization chain reaction (HCR) was triggered by the introduction of mutual partial complementary primers (H1,H2) to elongate the terminal into nanoscale duplex. As the electro-active iron porphyrins could intercalate into the grooves of double-stranded DNA (*ds*DNA) scaffold, multiple positive-charged Fe<sup>III</sup> *meso-tetra*(*N*-methyl-4-pyridyl)porphine (FeTMPyP) were under potentiostatic adsorption into porphyrin-*ds*DNA complex. Given FeTMPyP a highly efficient electrocatalyst for peroxide reduction, its groove binding as a biomimetic cofactor was validated possessing a high electrocatalytic activity with fast catalytic kinetics and stability. Using 4-chloro-1-naphthol (4-CN) as a proton donor, the electrocatalytic reduction of H<sub>2</sub>O<sub>2</sub> would oxidize it into insoluble benzo-4-chlorohexadienone, the mass of which instantaneously deposited on heterogeneous interface and aroused significant signal amplification of SPR response (Figure 1). The SPR increment was proportional to the concentration of *t*DNA, thus an ultrasensitive *e*-SPR-based DNA assay was developed with a *sub*-femtomolar detection limit. The proposed electrochemical methodology breaks the bottleneck of sensitivity in conventional SPR-based DNA analysis, showing a great promise in bioanalytical applications.

**Scheme 1.** Schematic illustration of the fabrication of *e*-SPR-based DNA assay.

**Figure 1.** The *e*-SPR response over time to 1.0 pM (a), 1.0 fM (b), and 0 M (c) *t*DNA in 10 mM pH 7.4 phosphate buffer saline.

# Materials Design for Lithium-Sulfur Batteries

Yi Cui,

*Department of Materials Science and Engineering, Stanford University.  
Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory.  
yicui@stanford.edu*

Rechargeable batteries have been a great success in powering consumer electronics. There has been a recent strong interest in applying rechargeable batteries to vehicle electrification and grid-scale storage. Novel battery chemistries are necessary for enabling these opportunities although they also present significant fundamental materials challenges. Here I will present our research progress on Li-S batteries, including understanding of  $\text{Li}_x\text{S}$  interaction with materials and designing nanomaterials for encapsulation and selective deposition of  $\text{Li}_x\text{S}$  species. We demonstrated excellent performance of Li-S batteries.

# Designing and optimizing novel electrode materials for rechargeable

## Na-ion batteries with high energy and low cost

Chuze Ma, Judith Alvarado, Jing Xu, Haodong Liu and Y. Shirley Meng

Sustainable Power and Energy Center, University of California San Diego

La Jolla, CA 92093, USA

With the pressing needs for economically feasible and environmentally benign energy storage technologies, Na-ion batteries have re-captured the attentions of the scientific communities due to its natural abundance and broad distribution. In this talk, we report our recent work on P2 and O3 types of layered Na transition metal (TM) oxides,  $\text{Na}_x[\text{Li}_y\text{Ni}_z\text{Mn}_{1-y-z}]\text{O}_2$  ( $0 < x, y, z < 1$ ), working as cathode materials in Na-ion batteries. In these compounds, the intercalation in the TM slabs and 2-D transportation of Na-ions occur concomitant with TM redox change during cycling. By identifying the interplay among structural evolution, electronic transition, and electrochemical reactions, the optimized composition is designed and significant improvement in battery performance is achieved. In addition to the cathode study, we have performed a systematic investigation on  $\text{Na}_2\text{Ti}_3\text{O}_7$  as anode in Na-ion batteries, since it is able to provide 177 mAh/g specific capacity at an ultra low voltage, 0.3 V. A new phase is identified upon full discharge. We have also optimize the material for better cycling retention and rate performance. The Na-ion full cell fabricated by our group with the two electrode materials above successfully demonstrates high voltage and reversibility, indicating a bright future for Na-ion batteries.

**Keywords:** novel electrodes; intercalation mechanism; Na-ion battery

# A Solid-Electrolyte-Enabled Lithium-Bromine Flow Battery

Peng Bai, Martin Z. Bazant

Massachusetts Institute of Technology

77 Massachusetts Avenue, Cambridge, Massachusetts 02139, USA

[pengbai@mit.edu](mailto:pengbai@mit.edu)

Water-stable solid electrolyte has become an enabling material for novel aqueous lithium-air batteries,<sup>1</sup> and hybrid-electrolyte lithium redox batteries,<sup>2</sup> in which lithium metal anode can be paired with various aqueous cathodes/catholytes via a nonaqueous-solid-aqueous hybrid electrolyte.<sup>2</sup> Here, we design and fabricate a lithium-bromine flow battery with the lithium ion conducting glass ceramic (LICGC) from Ohara, Inc. The proof-of-concept battery with a flat catalyst-free graphite electrode can discharge at 9mW/cm<sup>2</sup> with highly concentrated bromine catholytes, which in principle could provide a specific energy of 791.8 Wh/kg, superior to many existing cathode materials and catholytes. Scanning electron microscopy images reveal that both the organic electrolyte and the bromine electrolyte corrode the solid electrolyte plate quickly, leading to nanoporous pathways that can percolate through the plate, thus limiting the cell performance and lifetime. Further impedance analysis of samples immersed in different catholytes for two weeks confirms the deterioration of the conductivities of both the grains and grain boundaries. With improved solid electrolytes or membraneless flow designs, the lithium-bromine system could enable electric vehicles, by providing a critical high-power mode to high-energy-density (but otherwise low-power) lithium-air batteries.

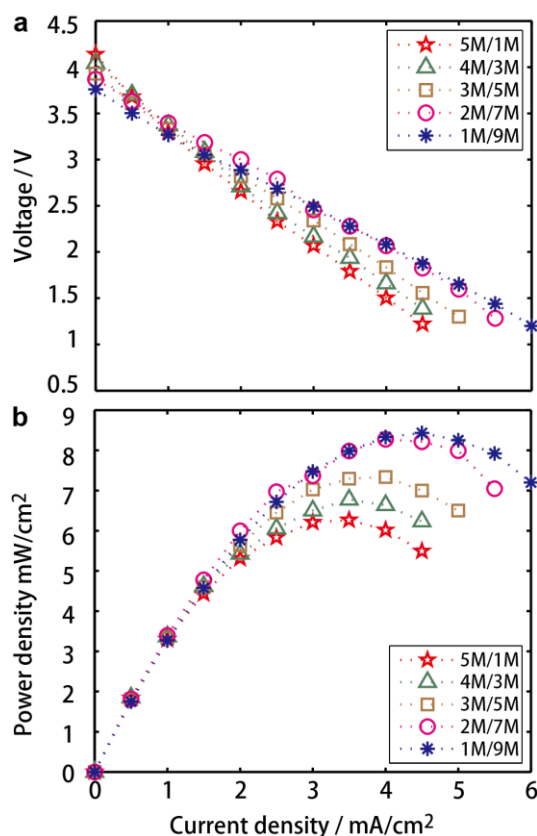

Figure 1. Polarization curves obtained from 5-min Galvanostatic discharging with different catholytes (a) and the corresponding power output (b).

# Functional Conductive Polymer Binders Enabled High-stability Cycling of Alloy Anodes

Gao Liu, Hui Zhao, Zhe Jia, Sang-Jae Park  
Lawrence Berkeley National Laboratory  
1 Cyclotron Rd., Berkeley, CA 94720, USA  
gliu@lbl.gov

A class of new functional conductive polymers is developed for electrochemical energy storage applications. Contrasting other polymer binders, these binders have tailored electronic structure, adhesive functional groups, and controlled polarity for ion transport. This class of materials is suitable as binders for high capacity alloy anode materials. Materials with high lithium storage capacity, such as Si and Sn based alloys, have recently been extensively studied for their applications as lithium-ion battery anodes. However, the large-volume change associated with lithiation and delithiation of these materials severely hinders the practical application. The functional conductive polymer binders maintain conductivity and mechanical integrity during the battery operation, implementing the conceptual idea of combining binding, electron conducting and ion conducting into one material to significantly improve the electrode cycling performance.

Figure 1. Molecular structure of the functional conductive polymer binders. a. First generation. b. Second generation. c. Third generation

We will cover the theory to develop the functional conductive polymer binders for Si and Sn alloy, three generations of the conductive polymer binders from our laboratory (Figure 1), and discuss the electric conductivity, adhesion and ion transport functionalities in these binders. Different Si based materials such as Si nanomaterial and SiO micron size materials are also used with these binders to fabricate electrode, and their performance characteristics reported. Electrode architectures are also very important for functional binders and alloy materials. The talk will also cover develop Si and conductive polymer electrode architectures including Si/binder composite particles, and in situ formation of Si network in the electrode. Conductive polymers with Sn materials system in lithium and Sodium ion batteries will also be discussed.

Lithium ion battery provides high energy and power density that uses into portable electronics and electric vehicle; however, the safety is a big issue and cannot be guaranteed due to different habits of users. In order to improve the safety performance of battery, a new technology called Self Terminated Oligomer Branched Architecture (STOBA) had been developed [1]. The STOBA is used to prevent the direct contact between anode and cathode when the battery suffers short problem. According to the literature [1], STOBA is an oligomer that homogeneously disperses into cathode slurry and electrochemically forms solid electrolyte interface (SEI) on cathode's surface. This SEI provides further isolated polymerization behavior in order to inhibit the decomposition of cathode material while battery gets short.

In this study, second generation of STOBA has been created. Figure 1 shows that the second generation of STOBA is polymerized by BMI/BTA oligomer (1<sup>st</sup> generation STOBA) and poly(phenylsiloxane) (PhSLX). The PhSLX is used to enhance the thermal and electrochemical stability of STOBA. In accordance with the results, this 2<sup>nd</sup> generation STOBA not only maintains high safety performance, but the cycle-ability at high temperature also increases.

The second generation of STOBA is a highly potential additive for application in electric vehicle.

# Oxygen Reduction and Evolution for Li-Air batteries: Role of the Electrocatalyst

Christoph Bondü, Christoph Molls, Philipp Reinsberg, Martina Hegemann, Helmut Baltruschat  
*University of Bonn*  
*Roemerstrasse 164, 53117 Bonn*  
*baltruschat@uni-bonn.de*

It is generally accepted that oxygen reduction in aprotic solvents leads to superoxide or peroxide, depending on the cation present. Since no bond breaking is occurring here, a dependence of the reaction on the electrocatalyst material is not expected.

We have carried out a detailed study involving differential electrochemical mass spectrometry (DEMS), electrochemical quartz crystal microbalance (EQCM) and the rotating disc electrode (RRDE) using a variety of smooth model electrodes (different noble metals and glassy carbon) and found marked differences on different materials. E.g., during oxygen reduction in a  $\text{Li}^+$  containing DMSO, reduction to super oxide and peroxide occur in well separated potential regions, whereas on Rh reduction occurs in a 2 electron process (as demonstrated by DEMS) in the whole reduction region. In the presence of Li, only a part of the formed reduction product ( $\text{Li}_2\text{O}_2$ ) is deposited on the electrode, another part is dissolved in the electrolyte:

From the deposit, oxygen can be evolved, the amount of which also depends on the electrode material. Whereas on Pt and Rh the oxidation occurs in only one oxidation peak (which is paralleled by oxygen evolution) close to the equilibrium potential, on Au three peaks are observed in a wide potential range. Astonishingly, no weight changes are observed by EQCM during oxygen evolution.

Comparative experiments in  $\text{Mg}^{2+}$  and other cation - containing electrolytes will also be presented.

# ***In situ* infrared spectroscopy on gold substrates to track film formation and intermediates in Li-ion and Li-air electrolytes**

Laurence Hardwick\*, Vivek Padmanabhan and Richard Nichols

*Department of Chemistry, Stephenson Institute for Renewable Energy, University of Liverpool,  
Liverpool, L69 7ZF, UK*

*\*hardwick@liverpool.ac.uk*

The main challenge for *in situ* infrared spectroscopy is to isolate the bands you wish to observe from the background bands arising from, for example the electrolyte. *In situ* attenuated total reflection surface-enhanced infrared absorption spectroscopy (ATR-SEIRAS) is particularly attractive for such spectroelectrochemical experiments [1]. ATR-SEIRAS uses a property of total internal reflection resulting in an evanescent wave. A beam of infrared light is passed through the ATR crystal for example, a ZnSe prism, in such a way that it reflects off the internal surface in contact with the sample (Figure 1). This reflection forms the evanescent wave which extends into the sample. Therefore, this allows one to investigate the surface region of the electrode and discriminate against the bulk electrolyte signal. In the ATR-SEIRAS set-up, part of the evanescent wave passes through a ca. 15 nm thin polycrystalline Au metallic film working electrode. The penetration depth through the Au film and into the electrolyte is typically between 0.5 and 2  $\mu\text{m}$ , with the exact value being determined by the wavelength of light, the angle of incidence and the indices of refraction of the relevant media. We have been developing and optimising this technique, particularly with relation to the Au film deposition, and will report on the study of electrochemical processes in non-aqueous electrolytes in systems that are of interest to understanding film formation and intermediates relevant to both Li-ion and Li-air batteries.

[xjhuang@iphy.ac.cn](mailto:xjhuang@iphy.ac.cn)

High-voltage spinel  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode material has specific energy (~640 mAh/g due to the high operation voltage of ~4.7 V. The relatively inexpensive Ni and Mn in  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  make this cathode material particularly desirable for large-scale applications. However, the real application is hampered by long-standing issues such as capacity degradation and poor first cycle coulombic efficiency. Despite of extensive studies of the issues, their associated mechanisms are not fully understood.

A detailed investigations of its local atomic-level structure with lithium extraction /insertion is reported. We observed two types of local atomic-level migration of transition metals (TM) ions in  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  particles during first charge via an aberration-corrected scanning transmission electron microscopy (STEM). The surface regions (~2nm) show an irreversible migration of TM ions into lithium tetrahedral sites to form a  $\text{Mn}_3\text{O}_4$ -like structure. The formation of these local structures and migration of TM ions are attributed to the destabilization of spinel  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode structure and evolution of a small amount of  $\text{O}_2$ . The surface  $\text{Mn}_3\text{O}_4$ -like structure contributes to the dissolution of TM ions. This structure as well as the rocksalt-like structures with heavy TM ions on the lithium pathways blocks the migration of lithium ions, resulting in building-up of charge transfer impedance and degradation of capacity. Since the  $\text{Mn}_3\text{O}_4$ -like and the rocksalt-like structures are formed as early as in the first charge to 4.9 V, they inevitably contribute to the poor first-cycle coulombic efficiency.

While a  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4/\text{Li}$  half cell shows excellent cycling performances at 25 and 55°C, the  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4/\text{MCMB}$  full cell has limited cycling life, especially at elevated temperatures. When the surface  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  was modified by coating and superficial doping, the cycling performance of the full cell with MCMB anode has been much improved and the coulombic efficiency of discharge/charge is also obviously increased. Theoretical calculations analyses reveal that the stability of O at surface layer is enhanced by those surface modifications and detailed analyses will be reported.

## **Abstract**

Lithium iron phosphate (LFP) has attracted tremendous attention as a next-generation electrode material in lithium rechargeable batteries for large scale energy storage systems due to the use of low-cost iron and chemical/electrochemical stability. While the lithium diffusion in LFP, the essential property in battery operation, is relatively fast due to the one-dimensional tunnel present in the olivine crystal, the tunnel is inherently susceptible to immobile anti-site defects which, if any, block the lithium diffusion and lead to the inferior performance. Herein, we demonstrate that the kinetic issue arising from the defects in LFP can be completely eliminated in a new olivine LFP, which we successfully synthesized for the first time. The doping in the olivine structure reduces the concentration of defects in the tunnel by 7 orders of magnitude. Moreover, it opens up a new lithium diffusion path along the [101] direction making the olivine LFP as a three-dimensional lithium diffuser. We also find that the intrinsic energy barrier for phase transition gets notably lower in the lithium excess olivine LFP. The fundamentally different nature of the new olivine than normal LFP additionally induces faster charging capability, lowering thermal solid-solution temperature and less memory effect.

# On the Influence of Mechanical Compression on the Impedance of Aged LiFePo<sub>4</sub> - Graphite Cells

Reinhold Koch<sup>1,2\*</sup>, Andreas Jossen<sup>1</sup>

<sup>1</sup> Institute for Electrical Energy Storage Technology, Technische Universität München, Karlstr. 45, 80333 Munich, Germany

\*reinhold.koch@tum.de

The impedance of a battery cell is influenced by a variety of parameters, like temperature and state of charge. The influence of mechanical force on a cell's impedance has not been reported so far as well as the interdependency of cooled and non-cooled cells during constrained operation.

We tested unconstrained cells, constrained cells which were liquid cooled during operation to 25 °C and cells which were intentionally insulated from the compression plates in order to eliminate the heat sink effect of cooling from large metal plates. After 1400 cycles we saw that the compression force had an immediate effect on the impedance of all three cells. Figure 1 shows an unconstrained cell which shows an almost immediate reduction in its impedance by around a factor of 4 with the maximum applied compression force of 7 bar. After releasing the cell the impedance “bounced back” again to its unconstrained values in an exponential way, i.e. the first change was very quickly, but it took several hours to reach the original impedance values.

The influence of cooled or insulated compression is most dominant when the cell is only constrained by a small compression force. Figure 2 shows that the capacity fade of an insulated cell which has been constrained with a small compression force of 0.5 bar has initially lower capacity as the unconstrained cell but overtakes it over of the lifetime. The biggest difference can be seen between the cooled and the non-cooled cell. Even if they have been constrained with the same compression force the cooled cell starts with a lower capacity and loses it much quicker than the insulated cell.

Figure 1: Influence of the compression force on the impedance of the LiFePo<sub>4</sub> pouch cell which was cycled under unconstrained conditions.

Figure 2: Capacity fade during constrained and non-constrained operation

The graphite electrode has a volume change of up to 7% during a charge discharge cycles, it is also the electrode most affected by aging.

Figure 3: Microscopic pictures of the graphite electrode of the used cells..

Figure 3 shows, that the formation of crystalline structures is stronger in constrained cells, where also the impedance change by compression as shown in Figure 1 was stronger.

# Computational data mining to boost the next generation batteries R&D: the composite electrode architecture

[alejandro.franco@u-picardie.fr](mailto:alejandro.franco@u-picardie.fr)

History teaches us that energy forms can be used to make practical things without knowing the nature or fully understanding the fundamentals of those energy forms. This affirmation is not unrealistic: Volta invented the first electric battery in 1800, almost 100 years before than electrons were discovered (credited to Thomson in 1897).<sup>1</sup> Therefore, the subsequent relatively fast penetration of rechargeable batteries in the market was mainly based on trial-error synthesis of materials and testing, and it is only since recent years supported by deep theoretical tools at the single material level.<sup>2</sup> But the automotive lithium ion battery (LIB) industry has reached a point where detailed optimization studies of the composite electrodes, made of complex mixtures of active material and additive particles with multiple sizes, binder and electrolyte, are vital to achieve high performance at low environmental and economic cost.<sup>3</sup> Then, the development of a theoretical framework helping on the design of efficient composite electrodes is urgently needed. Indeed, significant progress has been made in linking composite electrode structural properties to ionic transport and cell capacity response using computer-aided reconstruction of real electrode structure. However holistic approaches by combining electrode composition with fabrication parameters are crucial to produce results coherent with experiment.<sup>4,5</sup>

In this contribution we report an innovative multiscale computational modeling platform being developed in our laboratory, devoted to perform *in silico* data mining of composite electrodes architectures at multiple scales.<sup>6-11</sup> Such architectures are described in terms of particle and pore size distributions, three-dimensional binder spatial distributions and electrolyte solvent compositions. The platform combines multiple simulation paradigms: 1) stochastic discrete-particle methods devoted to describe the different steps along composite electrode fabrication and to predict the arising microstructure; 2) mesoscopic simulation approaches devoted to extract fundamental electrochemical and transport parameters; 3) continuum models devoted to gather these data in order to simulate cells and to detect electrodes architectures maximizing the cell capacity and energy density. The promising predictive capabilities of the platform will be illustrated, in comparison with experimental knowledge, within three concrete application contexts: all solid state LIBs with composite electrodes, lithium air batteries and lithium sulfur batteries.

Two main advantages of Lithium-air batteries are their very high energy densities and low costs. There are two approaches to the development of these batteries: the anhydrous system which uses an organic electrolyte, and the aqueous system which uses an aqueous electrolyte [1]. An advantage of the aqueous system is its safety since toxic or inflammable solvents are not used. The negative lithium electrode is separated from the aqueous electrolyte by a thin ceramic water and gas tight membrane which enables the battery to have an extremely low self-discharge rate. The interface between the lithium metal and the ceramic membrane plays an important role in the cycling performance of the aqueous lithium air cell. However, the poor or non-chemical stability of most ceramic electrolytes in contact with lithium metal limits the performance. A possible strategy to improve the interface between ceramic electrolyte and lithium metal might be by the use of polymer membranes [2].

Here, we study the effect of a polymer membrane between a ceramic electrolyte and lithium metal. Block copolymer electrolytes, such as polystyrene-block-poly (ethylene oxide) copolymer electrolyte (SEO) mixed with lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) salt, were used in this study. The ceramic electrolyte was a Lithium Ion Conducting Glass Ceramic (LICGC) purchased from Ohara Corporation (1 inch X 1 inch 150 $\mu$ m thick), and was used as the single ion conductor. In this work, lithium ion - lithium metal transfer from a lithium ion conducting polymer interface has been studied by impedance spectroscopy. Furthermore, in order to know if the sandwich polymer-ceramic cell showed an additional interfacial resistance, ionic conductivity experiments using electrochemical impedance spectroscopy were performed. Besides, polarization loss quantification at a lithium ion conducting polymer/single ion conductor interface was studied by DC current measurement by the Srinivasan et al method [3]. Finally, the interface between the ceramic and the polymer was studied by synchrotron hard X-Ray micro tomography experiments on symmetric lithium-sandwich polymer-ceramic cells, in order to confirm the intimacy of the ceramic and the polymer.

# The Influence of Anomalous Diffusion on the Impedance Response of LiCoO<sub>2</sub>|C Batteries

Salim Erol and Mark E. Orazem  
Department of Chemical Engineering  
University of Florida, Gainesville, FL 32611 USA  
[meo@che.ufl.edu](mailto:meo@che.ufl.edu)

This paper provides the results of impedance measurements on commercially available LiCoO<sub>2</sub>|C coin-type cells. The impedance response was shown to be extremely sensitive to temperature, state-of-charge, overcharge, and over-discharge. Interestingly, the impedance showed a persistent change to the electrochemical characteristics of a coin cell subject to overcharge; whereas, the electrochemical characteristics returned to normal for a coin cell subject to over-discharge. In early work, a measurement model analysis was used to show the reversibility of the impedance behavior of an over-discharged cell and the irreversibility of the impedance response of an overcharged cell.<sup>1</sup>

The impedance response of LiCoO<sub>2</sub>|C batteries has distinguishing characteristics that should, in principle, be associated with the electrochemical characteristics of the battery. A key feature is the low-frequency impedance that appears in a Nyquist plot as a straight line with an angle with respect to the real axis greater than the 45 degrees expected for a diffusion impedance.<sup>2</sup>

A process model for impedance analysis was developed in the context of reactions and transport processes that were hypothesized to govern the performance of the Li-ion battery. At the carbon electrode, lithium ions and solvent were considered to react to form a solid-electrolyte interphase (SEI). In addition, lithium ions were assumed to diffuse through the SEI to intercalate into the graphene layers. As these two processes involve an addition of currents, the corresponding impedances were considered to be in parallel. Anomalous diffusion of lithium ions was invoked at the LiCoO<sub>2</sub> electrode to account for the low-frequency line that had a slope steeper than that predicted by ordinary diffusion. This model was fit to all impedance data collected. The model provided a good description for impedance of batteries under normal operating potentials and temperatures. The contribution of anomalous diffusion was diminished at elevated temperatures, suggesting that the free-energy well associated with anomalous or sticky diffusion was shallow.

This work provides an alternative explanation for the slope of the low-frequency impedance response for LiCoO<sub>2</sub>|C cathodes that is steeper than that associated with Fickian diffusion impedance. This effect is clearly associated with the unique properties of the LiCoO<sub>2</sub>|C cathode as the low-frequency impedance response of other Li-ion battery cathodes, e.g., LiFePO<sub>4</sub> and LiMn<sub>2</sub>O<sub>4</sub>, show different behaviors.<sup>3</sup> Osaka et al.<sup>2</sup> have attributed this behavior to the different time constants for diffusion to particles of different sizes. The present work shows that anomalous diffusion may provide an alternative explanation that is specific to the properties of LiCoO<sub>2</sub>.

# How to make an ideal electrolyte based on bis(trifluorosulfonyl)imide-based ionic liquid for lithium-ion and lithium-sulfur batteries

Masaki Yamagata, Yukiko Matsui, Takuya Takahashi, Satoshi Uchida, and Masashi Ishikawa  
 Department of Chemistry and Materials Engineering,  
 Faculty of Chemistry, Materials and Bioengineering, Kansai University  
 3-3-35 Yamate-cho, Suita 564-8680, Japan  
 e-mail address: yamagata@kansai-u.ac.jp

Ionic liquids are still attractive candidates for use as electrolytes in electrochemical energy storage devices, because of their relatively low flammability and reactivity, and because of their electrochemical stability, wide liquidus temperature range, and acceptable ionic conductivity. We have reported a promising ionic liquid based on bis(fluorosulfonyl)imide (FSI<sup>−</sup>) for lithium-ion batteries since 2006. [1] This liquid with a lithium salt offers incredible charge-discharge performances; despite the relatively high viscosity of the electrolyte, it affords not only reversible and stable cycling but also rapid charge-discharge performance for both negative and positive electrodes. [2] Herein, we report the results from charge-discharge tests, focusing on the effect of the electrolyte component; LiFSI is used as the lithium source for the electrolyte and is compared to LiTFSI (TFSI<sup>−</sup> = bis(trifluoromethylsulfonyl)imide). In addition, we also investigate how the concentration of the lithium salts promotes the more stable and rapid charging-discharging of lithium-ion cell.

To clarify the effect of concentration of LiFSI on the dependencies of the discharge capacity retention of a graphite electrode in EMImFSI and EMImTFSI (EMIm<sup>+</sup> = 1-ethyl-3-methylimidazolium) on the charge-discharge C-rate, which were evaluated by determining the 5-cycle durability for each C-rate operation after primary charge-discharge cycling at the 0.1/0.1 C-rate, are summarized in Figure 1a. Here, the discharge capacity retention was calculated as  $C_x/C_2$ , where  $C_x$  and  $C_2$  are the specific discharge capacities for each cycle ( $x$ ) and for the second cycle (1.0 C-rate), respectively. The remarkable aspect in this figure is that the high concentration (1.46 mol dm<sup>−3</sup>) of LiFSI improves the output characteristics in comparison with 0.43 mol dm<sup>−3</sup> LiFSI/EMImFSI despite the electrolyte possessing a lower ionic conductivity, while 1.46 mol dm<sup>−3</sup> LiTFSI/EMImFSI decreases the rate capability of the graphite compared with 0.43 mol dm<sup>−3</sup> LiTFSI/EMImFSI. The high-concentration of LiFSI/EMImFSI also enables stable charge-discharge operation of the graphite electrode in low temperature. (Figure 1b)

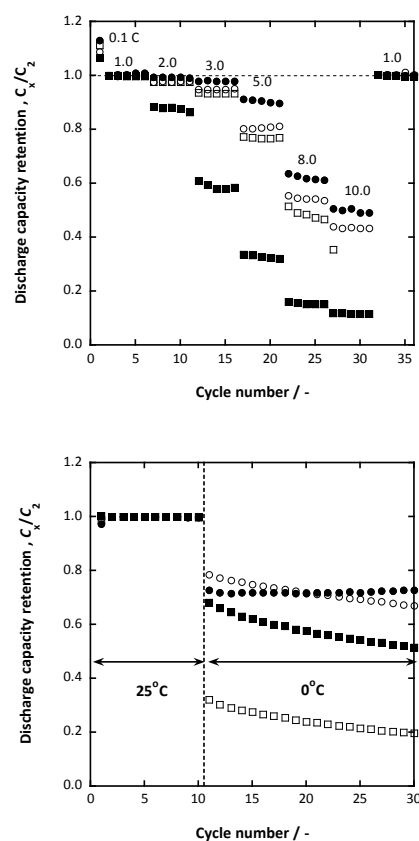

In the present study, we also discuss such an advantages of the use of high-concentration LiFSI/EMImFSI for lithium-sulfur battery.

The Li-O<sub>2</sub> battery has almost tenfold practical energy density than the current Li-ion battery; however, the use of Li-O<sub>2</sub> battery is restricted by poor cycle capability and low energy efficiency. In this work, RuO<sub>2</sub> nanoparticles was coated on the surface of  $\delta$ -MnO<sub>2</sub> by a facile sol-gel method, and the resulting composite was used as a high-performance cathode catalyst in Li-O<sub>2</sub> battery. After coating, we found that the discharge product Li<sub>2</sub>O<sub>2</sub> turn to form a thin film at the surface of MnO<sub>2</sub>, which could be easily formed and decomposed in discharge and charge processes. And with a soluble catalyst (LiI) added in the electrolyte, the battery show a high round-trip efficiency, with a low discharge and charge overpotential of 0.28 V and 0.58V, respectively, even at a high current of 3200 mA g<sup>-1</sup>. Excellent cycling stability can also be achieved in a fixed capacity (1000 mAh g<sup>-1</sup>, 180 times at 800 mA g<sup>-1</sup>) mode.

Recently, sulfate-based compounds have been widely investigated as cathode materials for lithium-ion batteries, and various samples [LiFeSO<sub>4</sub>F, Li<sub>2</sub>Fe(SO<sub>4</sub>)<sub>2</sub>, LiFeSO<sub>4</sub>OH, Fe<sub>2</sub>O(SO<sub>4</sub>)<sub>2</sub>, Na<sub>2</sub>Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>, *etc.*] have been explored.<sup>1</sup> Thanks to a greater electronegativity of sulfate [(SO<sub>4</sub>)<sup>2-</sup>] over phosphate group [(PO<sub>4</sub>)<sup>3-</sup>], the open-circuit voltage of these materials can be significantly increased. However, it should be noted that most sulfate-based compounds are soluble in water. This not only raises issues of proper material processing, but also challenges the stability of the material at highly humid environment.

In this study, tavorite-type LiFeSO<sub>4</sub>F was adopted to demonstrate the influence of relative humidity (RH) on its electrochemical performance. The compound was synthesized using an ionothermal method. The RH was manipulated over a range of 55–85% at 25 °C, and the corresponding structural change of the tavorite-type LiFeSO<sub>4</sub>F was monitored by X-ray diffraction (XRD). Surprisingly, nearly 80% of starting material was converted to FeSO<sub>4</sub>·H<sub>2</sub>O in less than 2 hours in 85% RH, and FeSO<sub>4</sub>·7H<sub>2</sub>O was identified as the main phase after 72 hours. Such degradation is of course less in the range of weeks in 55% RH. Aware of this issue, several sulfate-based compounds were tested under the same protocol, and it was found that the moisture sensitivity was inherent to most sulfate-based materials, whatever Li or Na-bearing, with a different degree of severity depending upon their structure and state of division. In contrast, we pleasantly found that Fe-based oxysulfate Fe<sub>2</sub>O(SO<sub>4</sub>)<sub>2</sub> are not moisture sensitive.

Therefore, to properly store and process sulfate-based materials, the relative humidity should be closely controlled. Means to mitigate the reactivity against water via surface coating with PEDOT/carbon, hierarchical nanostructuring, or others will be presented.

**Fig. 1.** Structural evolution of tavorite-type LiFeSO<sub>4</sub>F as a function of time in 85% RH at 25 °C

In recent years, lithium ion rechargeable batteries are commercialized as a preferable power source for portable consumer products. The performance of a lithium ion battery can be related to the solid electrolyte interface (SEI) layer formed on electrode surface and this film formation depends mainly on electrolyte composition<sup>1,2</sup>. Currently lithium-ion batteries mainly use either ethylene carbonate based (EC) electrolytes, which do not function at low temperature, or propylene carbonate (PC) based electrolytes which, due to their inability to form a solid electrolyte interface layer, are incompatible with graphite anodes. The use of additives, such as ethylene sulfite (ES)<sup>3</sup>, is an approach to addressing the PC electrode compatibility problem. In the current work, we report designing and screening of potential electrolyte additives derived from ES. To illustrate the potential of the selected additive and hence the screening technique, two representative electrolyte additive structures were selected, synthesized and experimentally tested. The mesocarbon microbead (MCMB) electrode showed an excellent electrochemical performance in a PC based electrolyte with 2% additives. The first cycle coulombic efficiency of the proposed additives was >84%, increasing to 99% after the second cycle. When compared with previously reported sulfur or halogen containing additives, the computationally designed additives resulted in better coulombic efficiency. CV, SEM, and XRD results confirmed the suppression of PC co-intercalation and electrode exfoliation. The results show that the method developed for screening potential additive structures works very well with PC-based electrolytes.

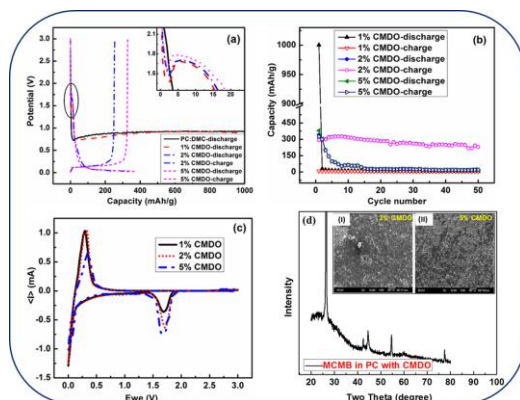

Figure 1. The first charge/discharge profile (a), cycling behaviors (b), cyclic voltammogram (c), and SEM images of MCMB in 1 M LiPF<sub>6</sub>/PC: DMC (1:1 v/v) with different concentrations of CMDO.

# Self-Discharge and Cycling Stability in the Li-S System: Where Every Cell Component Plays a Role

Matthew J. Lacey<sup>a</sup>, Anurag Yalamanchili<sup>a,b</sup>, Viking Österlund<sup>a</sup>, Fabian Jeschull<sup>a</sup>, Julia Maibach<sup>a</sup>, Carl Tengstedt<sup>b</sup>, Kristina Edström<sup>a</sup> and Daniel Brandell<sup>a</sup>

The Li-S battery has been the subject of renewed and intense interest in recent years by virtue of the very high energy density of the Li-S couple: fully assembled cells with energy densities of 500-600 Wh/kg – two to three times higher than the state-of-the-art Li-ion batteries – are widely thought to be a realistic proposition[1]. The greatest advances have come in the development of the positive electrode, with a wide variety of conducting host structures proposed to enable high utilisation of active sulfur species, decent rate capability and maintain stable cycling over hundreds of cycles.

However, the negative electrode or indeed consideration of the system as a whole is relatively rare. For example: it is increasingly deemed important that high active material loading in the positive electrode can be demonstrated, but the thickness of the Li anode and the volume of electrolyte used – both of these enormously important for energy density and cycle life in a full cell - are often absent from experimental sections. The ability of cells to withstand self-discharge when not in operation, which is perhaps the toughest test of effective control of polysulfide intermediates, is also rarely investigated.

In this work, we will present an overview of the variety of factors influencing self-discharge and cycle stability, from basic electrochemical and surface analysis studies of the redox shuttle in LiNO<sub>3</sub>-containing electrolytes, to measurement of the rate and reversibility of self-discharge over moderately long idle periods and the cycle stability of high-loading and high-efficiency cells with low excesses of electrolyte and lithium metal. New results from the extension of our existing work on functional binders[2] will also be presented within this context.

# Does Size really Matter? New Insights into the Intercalation Behavior of Anions into a Graphite Based Positive Electrode

Kolja Beltrop<sup>\*</sup>, Paul Meister, Olga Fromm, Martin Winter, Tobias Placke

University of Münster, MEET Battery Research Center, Institute of Physical Chemistry Corrensstr. 46, 48149 Münster, Germany

<sup>\*</sup>[kolja.beltrop@uni-muenster.de](mailto:kolja.beltrop@uni-muenster.de)

The increasing demand for large scale energy storage capabilities causes a big field of research to make the battery systems safer and environmentally benign. A promising approach is the replacement of conventional volatile and highly flammable organic solvent-based electrolytes by ionic liquids (ILs) as the main component of the electrolyte. ILs exhibit excellent properties such as a broad electrochemical stability window, a high thermal stability, non-flammability and a high ionic conductivity.[1] A further prevention of pollution is the application of carbon-based, transition metal-free electrode materials. Recently, “dual-ion” and “dual-graphite” cells were introduced which are composed of a lithium-incorporating anode and an anion incorporating graphite-based cathode.[2][3] During charge the ions intercalate into the electrode active materials and are released back into the electrolyte during discharge (see Figure 1). Since the cathode potential reaches and may even exceed 5 V vs.  $\text{Li/Li}^+$ , electrolytes that exhibit a high stability vs. oxidation are necessary. For that reason, ILs with their versatile properties were introduced and investigated. The state of the art electrolyte for this system is composed of a solution of lithium bis(trifluoromethanesulfonyl) imide ( $\text{LiTFSI}$ ) in *N*-butyl-*N*-methylpyrrolidinium bis(trifluoromethanesulfonyl) imide ( $\text{Pyr}_{14}\text{TFSI}$ ). In order to increase the specific capacity of this system, one main strategy is to focus on the intercalation of smaller anions than TFSI into the graphite structure. In this context, the major challenge is the synthesis of ILs or mixtures of ILs with organic electrolytes consisting of small anions to provide an electrochemically stable electrolyte. Interestingly, not only the size and shape of the intercalated anions plays a major role in view of onset potential for anion uptake as well as discharge capacity. Instead, also more complex coherences such as ion association, self-aggregation of ions as well as solvent co-intercalation have to be taken into consideration. In this work, we investigate the electrochemical intercalation of anions with different shapes and sizes from either IL or organic based electrolytes into a graphite-based cathode. Against this background, the influence of side chain modifications within the anion structure on the intercalation behavior was studied using different electrochemical analysis techniques. Therefore, in this contribution we will give new insights to the question if the anion size is the main issue to tailor the reversible capacity for anion intercalation.

# Novel Electrochemical-Thermal Modeling for Lithium-ion Battery Design based on a Fast Reduced P2D Electrochemical Model

Nan Lin, Georg Lenze, Urike Krewer

*Institute of Energy and Process Systems Engineering, TU Braunschweig*

*Franz-Liszt-Strasse 35, 38106 Braunschweig, Germany*

[n.lin@tu-braunschweig.de](mailto:n.lin@tu-braunschweig.de) [g.lenze@tu-braunschweig.de](mailto:g.lenze@tu-braunschweig.de) [u.krewer@tu-braunschweig.de](mailto:u.krewer@tu-braunschweig.de)

Lithium ion batteries have been intensively investigated regarding novel electrode materials and the processes in the cell. They are getting more and more widely applied for powering electric vehicles and electronic devices. Practically, thermal management of lithium-ion batteries has become a major topic. Recently first coupling models which combine an electrochemical model with a 3-D thermal model have been developed to contribute to battery design and thermal management [1]. However, they cannot be applied into realistic case optimization with multiple parameters, because the calculation efficiency of these models cannot satisfy the present requirement in industries [2].

In this work, we combine a 3-D thermal model with a reduced P2D electrochemical model, with respect to an Al-doped LMO pouch cell. The cell was manufactured in the Battery LabFactory Braunschweig – enabling validation and to determine the full composition and geometric parameters of the cell. The classical P2D model was reduced to a 1-D model by using an analytical solution for solid diffusion and was coupled with a 3D-CFD thermal model. The model shows the temperature, potential and concentration distribution of the whole pouch cell under various discharge rates. Moreover, the thermal analysis with applied cooling strategy is shown to serve primary battery design. The simulation results assist to analyze the relationship between thermal behavior and electrochemical behavior in order for a further understanding and optimizing of internal parameters and geometry. The present model with its reduction is sufficiently fast and allows us to conduct real-time multi-parameter and multi-case optimization.

Figure 1 (left) shows the temperature distribution results for clamp cooling and 5C discharging of an Al-doping LMO pouch cell. Due to the clamp cooling path, obvious temperature differences from different cell positions are observed. As a consequence, a better thermal management is needed, since cell temperature affects the temperature-dependent electrochemical behavior of the cell. On the right hand side, we can see the validation of the electrochemical sub-model. The simulation results make a good agreement with the experimental data, as well as in a short calculation time. The introduced good coupling model can well assist with better understanding the temperature-dependent battery process and practical battery design for industrial satisfaction.

# Functional Binders – SEI Formers, Dispersants and Local Electrolyte Components

Fabian Jeschull, Matthew. J. Lacey, Daniel Brandell  
Department of Chemistry – Ångström Laboratory, Uppsala University  
Box 538, 751 21 Uppsala, Sweden  
Fabian.Jeschull@kemi.uu.se

Electrode binders have long been considered as components which merely provide good adhesion to the current collector and maintain the physical integrity of the composite electrode in Li-ion batteries. In the pursuit of larger gravimetric energy densities, longer lifetime and lower cost – for instance for electrification of transport – new negative and positive electrode materials such as silicon and sulfur are explored. These novel cell chemistries pose new demands on the binder, challenging the conventional (and ecologically problematic) poly(vinylidene difluoride) (PVdF)[1,2,3].

For negative electrode materials, water-based alternatives, particularly carboxymethyl cellulose sodium salt (CMC-Na), poly(acrylic acid) (PAA) and its sodium salt (PAA-Na), form more favorable solid-electrolyte interface (SEI) layers and tolerate larger volume changes, thus extending the cycle life considerably in many Li-battery cell chemistries utilizing graphite or silicon. They have proven themselves beneficial beyond the conventional merits of an electrode binder and have therefore recently received significant interest in the battery research field.

In a previous investigation by our group [4], CMC-Na and PAA-Na are compared with PVdF-based polymers as binders in graphite electrodes in an aggressive, propylene carbonate-rich solvent. Appropriate surface coverage and low degrees of swelling were identified as key parameters for the stability of graphite in this environment, which could be provided by the alternative binder systems. We have very recently extended this concept to ether-based Li-S cells and silicon electrodes.

This work demonstrated that careful choice of the binder can enable reversible cycling of graphite anodes at high capacity and with high coulombic efficiency in purely ether-based electrolytes (*Fig. 1a*). This has strong implications for the Li-S battery system, where so far only a limited number of studies have addressed the negative electrode and where a vast excess of lithium is generally required in order to achieve acceptable cycle life [5].

For silicon electrodes, the effect of surface coverage on the cycling stability of silicon electrodes is strongly dependent on the amount and type of binder chosen, due to the large volume expansion during the alloying process and the resulting electrode disintegration. This highlights the implications of surface interactions between the binder and other composite electrode components (*Fig. 1b*) and sheds new light on the relation between electrode compositions and cell failure.

If new ‘beyond Li-ion’ technologies are being proposed or developed using alternative cathodes (Li-O<sub>2</sub>, Li-S) which, by themselves, are challenging, a common point with all these technologies is the use of Li metal, a typical ‘pre Li-ion’ anode. Although it offers the highest theoretical capacity among all lithiated anodes, its implementation in commercial Li-metal batteries has been successful using polymer electrolytes only. A major drawback of these electrolytes being their room temperature performance and, in general, below 60-80°C, Shin *et al.* [1] proposed the use of ionic liquids (ILs) as non-volatile and non-flammable plasticizers, allowing the decrease of Li-metal polymer battery operation down to 40°C [2]. On the other hand, several reports pointed out the excellent lithium plating (and cycling) behavior, using liquid, ILs-based electrolytes [3, 4]. ILs constitute a wide family of chemicals with properties that differ significantly. Their chemistry influence their bulk properties, but also the interfacial properties with Li metal (formation of the so-called Solid Electrolyte Interphase (SEI) [5]). Finally, in case liquid electrolytes are used, hard contact points can result from the separator and alter the SEI evolution either favorably or detrimentally, depending on the ionic liquid. Beside low and room temperature operation, dendrite formation is a major concern when dealing with Li metal electrodes. If, at high charging currents, dendrites growth is rather well understood as resulting from ionic species transport [6,7], their formation, especially at lower current densities, is more debated as the SEI, cell assembly and any defect, all participate in triggering dendrites growth.

An overview of Li-metal electrode use in both solid and liquid IL-based electrolytes will be given with emphasis on the conditions allowing homogeneous Li metal deposition and long term cycling.

## Abstract

Recent commercial lithium ion batteries (LIBs) consists of layer-type lithium cobalt oxide, spinel  $\text{LiMn}_2\text{O}_4$  or  $\text{LiFePO}_4$  as the cathode and graphite as the anode material, and electrolyte consists of a non-aqueous Li- ion conducting solution or immobilized gel-polymer as an electrolyte. LIBs with an operating voltage of 3.6 V are extensively used in the present-day electronic mobile devices. However, for high-power applications like back-up power supplies and electric/hybrid electric vehicles, the LIBs need to satisfy several additional criteria, such as cathode must show high charge potential and electrode material must show mixed ion conduction. Finally cost-reduction, safety-in-operation at high current charge/discharge rates and low-temperature cycling are needed for practical applications.

In my talk, I will discuss our group recent electrochemical properties of selected V-based cathodes,  $\text{LiVPO}_4\text{F}$ ,  $\alpha_1\text{-LiVOPO}_4$  and novel,  $\text{MVO}(\text{HPO}_4)(\text{C}_2\text{O}_4)_{0.5}$ ,  $\text{M}_2[(\text{VO})_2(\text{HPO}_3)_2(\text{C}_2\text{O}_4)]$  ( $\text{M} = \text{Li, K, Na}$ ). They were prepared by carbothermal reduction method and solvo-hydrothermal method followed heat treatment. Materials were characterized by Rietveld refinement X-ray diffraction, X-ray photo electron spectroscopy, SEM, density and BET surface area methods. Electro analytical studies were carried out using cyclic voltammetry, galvanostatic cycling and electrochemical impedance spectroscopy techniques. The charge cycling profiles shows a flat potential of 4.2V vs. Li, which higher than  $\text{LiFePO}_4$  cathodes. Comparative cycling performance and advantages of matrix elements,  $\text{HPO}_4$  and  $\text{HPO}_3$  groups on electrochemical cycling are discussed in detail.

Key words: Cathodes; Lithium ion batteries; characterization techniques.

# Unexpected Cycle Aging of a Commercial 18650 Cell

Po-Han Lee, She-huang Wu

Department of Materials Engineering, Tatung University  
No.40, Sec. 3, Zhongshan N. Rd., Taipei City 104, Taiwan (R.O.C)  
ud7878@hotmail.com

The aging mechanism of a lithium ion battery comprised of a  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2/\text{LiMn}_2\text{O}_4$  composite positive electrode and graphite anode at 2C rate had been studied with an incremental capacity technique [1, 2]. The results indicate that capacity fade is mainly caused by loss of inventory (LLI) during the first stage then followed by loss of active material (LAM) in the second stage. However, the degradation mechanisms and their correlation with cell performance fade are not only dependent on the cell chemistry but also on the cell design and manufacture technique.

Commercial 18650 lithium ion cells containing a blend of  $\text{LiNi}_{0.5}\text{Mn}_{0.3}\text{Co}_{0.2}$  (NMC) and  $\text{LiMn}_2\text{O}_4$  (LMO) materials as cathode and graphite as anode with a nominal capacity of 2.15 Ah were used in this study. The capacity retention of the commercial cells was performed by charging at 0.5C followed by a constant voltage step until current was lower than 0.04C and discharging at 0.2, 0.5, 1.0, 2.0C rates, respectively. The results, shown in Fig. 1, manifests that a longer cycle life is achieved at the higher C-rate (2C), which is contrary to the generally accepted notion that high C-rate will accelerate cell aging. To reveal the reasons, cells were cycled at 0.04C for 1 cycle after every 100 cycles and the plots of the incremental capacity analysis of the 0.04C cycles of the cells discharged with 1 and 2C rates are shown in Fig. 1(b) and (c), respectively. The 3.5V peak which can be attributed to intercalation of  $\text{Li}^+$  ions into graphite to form  $\text{LiC}_x$  shifts to higher voltage and its intensity decreases with number of cycle. It suggests that the capacity loss is contributed by LLI and LAM of anode, whereas the significant decreasing at 3.6V peak indicates the degradation of NMC and LLI. The peaks at 3.95 and 4.05V are the characteristics of  $\text{LiMn}_2\text{O}_4$ . It can be observed that the peak at 3.95V decreases significantly while slight change in intensity of the 4.05V peak upon cycling. That can be caused by the loss of anode material and the reaction between  $\text{LiC}_{12}$  and  $\text{LiC}_6$  come up early. It also induces the appearance of the peak at voltage between 3.8 and 3.88V. The cell cycled with 1C discharging rate shows a prompt loss of anode material that can be manifested from the sudden decreasing of the 3.5V peak between 300<sup>th</sup> and 400<sup>th</sup> cycles (Fig. 1(b)). However, the lowering of the 3.5V peak is less significant for the cell cycled with discharging rate of 2.0C. That suggests the unexpected results can be attributed to the differences in rate of anode material loss upon cycling with various discharging rates. The reasons for the different rates of anode material loss may be caused by the different extent of  $\text{Li}^+$  ion extracted from intercalated graphite when cells were discharged at various rates. The suggestion is hoped to be supported by the post-mortem analysis of the cells cycled at various discharging rates.

aponrouch@icmab.es

The development of a rechargeable battery technology using light electropositive metal anodes would bring in a breakthrough in energy density.<sup>1</sup> For  $M^{n+}$  charge carriers, the number of ions that must react to achieve a certain electrochemical capacity is diminished by two ( $n=2$ ) or three ( $n=3$ ) when compared to  $Li^+$ .<sup>2</sup> Proof-of-concept has been achieved for highly polarizing  $Mg^{2+}$  with complex electrolyte compositions to enable electrodeposition (plating) and covalent host cathodes to diminish coulombic interactions.<sup>3,4,5</sup> An analogous technology based on  $Ca^{2+}$  would hold promise for faster reaction kinetics (and thus better power performance) due to its lower polarizing character, and be attractive on cost and environmental grounds, but the electrodeposition of calcium was thought to be impossible to date<sup>6</sup> and research mostly restricted to non rechargeable systems.<sup>7,8,9,10</sup> Here we demonstrate the feasibility of calcium plating using conventional organic electrolytes, such as those used for the Li-ion technology. The parameter affecting the reversibility of the plating/stripping process upon cycling will be discussed. These results constitute the first step towards the development of a new rechargeable battery technology using calcium anodes.<sup>11</sup>

Large-size lithium-ion batteries (LIBs) have been developed for the use of battery electric vehicles. For BEVs, the long cruising distance and short charging time are imperative. The former is determined by the energy density (the product of battery voltage and battery capacity) and the latter is determined by the power density (the product of voltage and current). Present LIBs for BEV-use possess large power densities by the sacrifice of energy densities. On the other hand, recent LIBs widely used for portable devices have large energy densities with small power densities. In the case of LIBs for BEV-use, shorter charging times are necessary since the time to put petrol in present gasoline car is within several minutes. In order to shorten the charging times, reduction of internal resistances in the LIBs for BEV-use must be required.

The internal resistances in LIBs are composed of various processes; (1) electron transfer between a current collector and active material, (2) electron transport in a composite electrode, (3) ion (lithium ion and counter anion) transport in a composite electrode, (4) lithium-ion transfer at interface between active material and electrolyte, (5) lithium-ion diffusion in active material, (6) ion (lithium ion and counter anion) transport in bulk electrolyte through separator. Among these six resistances, we have focused on (3) and (4).

Here we report the charge transfer and ion transport resistances at graphite electrodes. For the former issue, we will show the factors which determine the charge transfer resistances, and for the latter issue, we will show the ion transports are influenced by the pore sizes, in particular, meso- to macro-pores.

# Fundamental Analysis of Lithium-ion Battery Performance and Degradation in Context of Particle Size Distribution

Fridolin Röder, Ulrike Krewer

*Institute of Energy and Process Systems Engineering, TU Braunschweig  
Franz-Liszt-Strasse 35, 38106 Braunschweig, Germany  
[f.roeder@tu-braunschweig.de](mailto:f.roeder@tu-braunschweig.de), [u.krewer@tu-braunschweig.de](mailto:u.krewer@tu-braunschweig.de)*

Lithium-Ion battery electrodes consist of active material particles with varying size. This heterogeneity is quantified using particle size distribution (PSD). Even though it is reported that the distribution of the electrode material is precisely adjustable by modern production processes [1], the effect of the actual PSD on battery performance and degradation is often neglected in theoretical model based analysis.

In this work we present a fundamental model-based analysis of the effect of particle size distribution (PSD) on Lithium-Ion battery performance and degradation. We use a mathematical electrode model with distributed particle size to analyze the influence of shape and scale of the distribution. In figure 1 (left), distributions with different shape but almost equal mean radius are shown. Performance of electrodes with the respective distributions are analyzed using the electrochemical model. Figure 1 (right) shows the electrode potential vs. capacity and illustrates the significant impact of a distribution's shape. It can be seen that the electrode capacity significantly decreases with diversification of the distribution. Moreover, we identify different dynamical charging behavior of the particles in such a system. The results show how the interaction between the large and small sized particles in this composition can be explained and why this leads to uneven surface overpotentials and reaction rates. The observations open up novel approaches to investigate and understand also degradation of such particle based electrodes. We therefore investigate the degradation caused by the change of the PSD during battery usage, which is caused by particle cracking or agglomeration. This change of the distribution is modeled based on a distribution evolution equation [2].

The presented work indicates that the PSD and its change considerably impacts the performance and degradation of Lithium-Ion batteries. We suggest that the distributions and its evolution should be of particular interest for future studies of degradation of particle based electrodes.

# Synthesis and electrochemistry performance of Na[FeTi]O<sub>4</sub> as anode material for sodium-ion batteries

Jun Wang, Xin He, Haidong Liu, Tim Risthaus, Jie Li

MEET Battery Research Center/Institute of Physical Chemistry, University of Muenster  
Corrensstrasse 46, 48149 Muenster, Germany  
[jie.li@uni-muenster.de](mailto:jie.li@uni-muenster.de)

In the past two decades, lithium-ion batteries (LIBs) have been successfully used in mobile electronic devices. However, material costs continuously increase as lithium reserves are limited both in amount and geographical location. The interest in sodium-ion batteries (NIBs) has been on the rise in recent ten years and NIBs currently constitute the most attractive alternative chemistry for rechargeable batteries. NIBs are also eligible for large-scale production, because sodium is much cheaper and more abundant in the earth's crust, and the potential of sodium metal is only 0.3 V higher than that of lithium metal.<sup>1, 2</sup> Therefore, supplementary to the progress in the field of advanced LIBs, it is also imperative to develop NIBs in order to provide sufficiently safe and low-cost energy storage devices.

Recent advances in the development of NIBs are mostly on positive electrode materials. Numerous cathode compounds capable of efficient Na<sup>+</sup>-ions (de)insertion have been reported so far.<sup>3</sup> However, much less studies have focused on the anode materials for NIBs.<sup>4</sup> Although hard carbonaceous materials could show the ability to reversibly (de)insert Na<sup>+</sup> ions, these materials display worse capacity retentions than their lithium counterparts.<sup>5</sup> Titanium (Ti)-based intercalation compounds have been proved to be another important class of anode materials for NIBs in terms of their safety properties and low potentials.

**Figure 1.** *In situ* XRD analysis of the (de-)sodiation mechanism of Na[FeTi]O<sub>4</sub> materials. XRD patterns obtained upon discharge and charge processes of the Na[FeTi]O<sub>4</sub> electrode.

We report a novel class of Fe and Ti-based Na[FeTi]O<sub>4</sub> anode materials for NIBs. The material exhibits an orthorhombic structure, which shows a reversible capacity of 181 mAh g<sup>-1</sup> under a current density of 17.7 mA g<sup>-1</sup> (0.1 C) and good cycling performance (more than 95% capacity retention after 500 cycles at 2 C). The novel class of orthorhombic Na[FeTi]O<sub>4</sub> could be promising anode materials for NIBs with low cost and long cycle life. *In situ* X-ray diffraction (XRD) results indicate that Na<sup>+</sup> ions behave in topotactic insertion and extraction manners inside this material (Figure 1). Meanwhile, gas evolutions during the initial redox process are analyzed by an *operando* mass spectrometry technique. The result suggests that the Na[FeTi]O<sub>4</sub> material exhibits an enhanced safety (Figure 2).

**Figure 2.** Cyclic voltammetric plot of the Na/Na[FeTi]O<sub>4</sub> cell for *operando* MS analysis (0.01-2.5 V; 0.1 mV s<sup>-1</sup>) and the evolving gas species with molecular weights of 2 (black), 15 (red), 27 (dark yellow), 28 (blue), 41 (magenta), 32 (olive) and 44 g mol<sup>-1</sup> (gray) formed upon the initial redox process. Inset: Optical image of the *in house* developed cross-shaped cell.

The solid electrolyte interphase (SEI), which is formed on the anode of a lithium-ion battery during the initial cycle(s), provides lithium ion conduction and electrical passivation, and thus allows stable lithium ion intercalation without further electrolyte reduction. To tailor this interphase for more efficient protection, additives such as vinylene carbonate (VC) or fluoroethylene carbonate (FEC) are added to the electrolyte which is usually composed of LiPF<sub>6</sub> in cyclic (e.g., EC) and linear alkyl carbonates (e.g., EMC).

In this study we use electrolytes of LiPF<sub>6</sub> in pure VC and FEC in order to understand their influence on the SEI, which is characterized with XPS and FTIR. While VC yields Poly-VC at coverages which strongly increase with the VC concentration, FEC yields next to large quantities of LiF also some polycarbonate, which, however, does not scale with the FEC concentration. Furthermore, we use on-line electrochemical mass spectrometry (OEMS), which was set-up for the analysis of Li-O<sub>2</sub> cells [1] and further modified to study the gassing behavior of Li-ion cells [2,3]. Figure 1a displays that both VC and FEC evolve mainly CO<sub>2</sub> at potentials of  $\approx 2$  and  $\approx 1.5$  V<sub>Li</sub>, respectively, i.e., substantially more positive than the C<sub>2</sub>H<sub>4</sub> gas evolution at  $\approx 0.9$  V<sub>Li</sub> from EC reduction [4]. Interestingly, CO<sub>2</sub> was one of the earliest SEI-additives studied in Li-ion batteries [5,6]. As shown in Figure 1b, continuous PC (propylene carbonate) intercalation and reduction is avoided by addition of 1 atm CO<sub>2</sub>, and stable cycling comparable to cells with 2% FEC is obtained. Thus, this study will focus on a comparison of the efficacy and the mechanistic working principles of currently employed additives with that of the direct addition of CO<sub>2</sub>.

**Figure 1:** (a) Gas evolution rate per carbon electrode surface area as a function of reduction potential of a pure VC and FEC electrolyte (1M LiPF<sub>6</sub>). (b) Galvanostatic cycling performance at 25°C of LFP/graphite electrodes with 1M LiPF<sub>6</sub> in EC/EMC (3:7) or PC/EMC (3:7) without and with 2% of VC, 2% FEC, or under 1 atm CO<sub>2</sub>. The cells were cycled between 3.8 V and 2.7 V at rates of C/20 (1<sup>st</sup> cycle) and C/10 (2<sup>nd</sup> and 3<sup>rd</sup> cycle), followed by 37 cycles at C/5.

# Homogeneous Catalysts for Li-Oxygen Cells

James T. Frith, Luyi Yang, Nuria Garcia-Araez, John R. Owen  
 University of Southampton  
 B29, Highfield campus, SO17 1BJ, UK  
 J.Frith@soton.ac.uk

Lithium-oxygen cells have a theoretical specific energy of around 5 times that of Li-ion cells, this makes them ideally suited for powering electric vehicles. However early lithium-oxygen cells, as proposed by Abraham and Jiang [1], have faced a series of problems. Primarily these problems were due to the instability of commonly used carbonate electrolytes with superoxide [2-3], a product of oxygen reduction. The introduction of electrolytes that are stable to superoxide attack [4-5] has led to great improvements in cell performance. However the insoluble and insulating nature of the primary discharge product, lithium peroxide, limits cell capacity and adversely affects the cycle life of cells [6].

This work examines the relationship between homogenous catalysts and the resulting enhancements seen in cell performance. In particular the increase in the practical cell capacity seen when employing ethyl viologen as a homogeneous catalyst for the discharge reaction was investigated [7-8]. The enhancement seen in the cell capacity is a direct result of the mediator action of the ethyl viologen which promotes the 2-electron reduction of oxygen while at the same time moving the site of oxygen reduction away from the electrode surface (Fig 1). Improvements to the round trip efficiency were also investigated using homogeneous catalysts for the charge reaction, in a similar manner to that demonstrated by Bruce *et al.* [9].

As well as looking into the enhancement of cell performance seen when using homogeneous catalysts the role of the electrolyte was also investigated. The electrolyte was found to play an important role in determining the action of homogeneous catalysts.

# Understanding Na-O<sub>2</sub> Electrochemistry in Non-aqueous Na-O<sub>2</sub> Batteries

Nadège Bonnet-Mercier, Raymond A. Wong and Hye Ryung Byon  
Byon Initiative Research Unit (IRU) / RIKEN  
2-1 Hirosawa, Wakoshi, Saitama, 351-0198 Japan  
nadege.b@riken.jp and hrbyon@riken.jp

Metal-oxygen (or metal-air) batteries have been considered as one of promising energy storages to fulfill the increasing demand on high energy density system for applications from portable electronic devices to electric vehicles. The non-aqueous sodium-oxygen (Na-O<sub>2</sub>) battery is particularly attractive because of its expected low cost since Na is abundant element on earth and its reasonably high specific energy (~1.1 kWh/kg, which is almost twice of lithium-ion batteries). In addition, the first demonstration of Na-O<sub>2</sub> battery revealed moderate overpotential for both discharge and charge [1] unlike the Li-O<sub>2</sub> battery suffering from huge overpotential for charge [2]. However, there is little knowledge for Na-O<sub>2</sub> electrochemistry, which is associated with low Coulombic efficiency and poor cycle life in the Na-O<sub>2</sub> battery [1, 3-4].

We studied Na-O<sub>2</sub> electrochemistry using carbon nanotubes (CNT) as positive electrode and diglyme/Na trifluoromethanesulfonate as electrolyte. The Na-O<sub>2</sub> cell delivers a capacity of around 2500 mAh/g<sub>CNT</sub> as shown in Figure 1. During discharge, cubic products with micrometer size are formed on the CNT (Figure 1 inset), which are completely decomposed during charge. The XRD pattern in Figure 2 demonstrates that the primary discharge product is sodium superoxide crystal (NaO<sub>2</sub>). The NaO<sub>2</sub> can be formed at a thermodynamic potential of 2.27 V (vs Na/Na<sup>+</sup>).

Figure 1 shows discharge and charge plateau at 2.15 V and 2.35 V, respectively. This demonstrates moderate discharge and charge overpotential in a range of 0.08~0.12 V. Online electrochemical mass spectroscopy (OEMS) analysis confirms the 1e<sup>-</sup> process for both discharge and charge (up to 80%), where the O<sub>2</sub> gas evolution is predominant. However, over 80% charge, the potential drastically increases up to 4.0 V and H<sub>2</sub> and CO<sub>2</sub> start evolving. The XRD in Figure 2 reveals no reflection of NaO<sub>2</sub> after 80% charge, indicating that the Na-O<sub>2</sub> electrochemical reaction terminates within 80% charge. The resultant low Coulombic efficiency arises from side reaction (e.g., instability of electrolyte and CNT) during discharge. In addition, formation of Na dendrites in the negative electrode is observed after charge. These unintended reactions eventually lead to poor cyclability. We discuss detailed analyses of side reactions and strategies to improve cycling performance in the presentation.

cnlin0908@itri.org.tw*

In order to overcome the issues of sulfur insulation and polysulfides dissolve in electrolyte on lithium-sulfur (Li-S) battery, the research focus on a micro- and macroscopic structure design of activity materials and cathode electrode. First, the nano-sized sulfur particles were dispersed on the carbon black matrix using an in-situ redox reaction. The sulfur-carbon (S-C) nanocomposite morphology most likely the *hylocereus undatus* structure (Fig. 1). Because the smaller S particles have larger specific surface area, it may lead better S utilization and faster charge/discharge rate. The S-C nanocomposite has 78 wt % S loading. Second, we designed a mille-feuille structure with inserting S-C nanocomposite between carbon membranes with high porosity and high conductivity (Fig. 2). The mass loading of the S cathode was 2~3 mg/cm<sup>2</sup> and higher than the most sample reported in the literature. The designed electrodes not only provide the polysulfide migration in the electrolyte but also inhibit the Al foil corrosion at the high operating voltages. In addition, a dynamic battery management system was also used in this studying, and these complex designs and fabrication processes compromise the utilization efficiency of S and long cyclic life. The charging/discharging results show that the S-C electrode can deliver specific discharge capacity of 1250 mAh/g at 0.5C and also demonstrate a long cycle life exceeding 1000 cycles. To our knowledge, the extremely low capacity-decay rate (0.04% per cycle) may be the best performance in this field.

s.fujiki@samsung.com

All-solid-state lithium-ion battery (SSB) with a non-flammable solid electrolyte is one of the promising candidates for next-generation high performance power source because of its low risk of safety concerns. Sulfide-based lithium ion-conductive solid electrolytes have attracted growing interests to be used in such SSBs, because of their non-flammability, high ionic conductivity and electrochemical stability.<sup>1, 2</sup> However, there are still some serious issues to overcome before the realization of SSB for practical applications. Since the ionic and electric conduction paths are given by the contacts of solid electrolyte particles, the cell impedance is typically higher than those of conventional liquid electrolyte lithium-ion batteries. Consequently, most of the SSBs need an external pressure during the charging and discharging processes.<sup>3</sup> Also, some literatures have suggested the necessity of a thin buffer layer on the cathode surface to prevent the mutual diffusion of atoms between the metal oxide and sulfide electrolyte.<sup>3,4</sup> Thus, in order to create a SSB of practical size, we adopted  $\text{Li}_2\text{O-ZrO}_2$  (LZO) thin layer coating on the cathode material for reducing the solid-solid interface resistance.<sup>5</sup> Although a number of basic scientific studies have already been reported, development of a practical size device is still premature.

We fabricated a large size SSB by a slurry coating method from the composite slurries containing polymer binders. The battery attained the capacity of 500 mAh in a single cell. Total capacity of a stacked cell was 2000mAh with the power density of 175Wh/kg. The single cell retained the capacities above 80% after 300 cycles without an artificial external pressure (Figure 2). In this work, we demonstrated the applicability of the sulfide based electrolyte for a practical size SSB. Although further development is still needed, SSBs hold a great promise as next generation energy storage.

raymond.wong@riken.jp, hrbyon@riken.jp

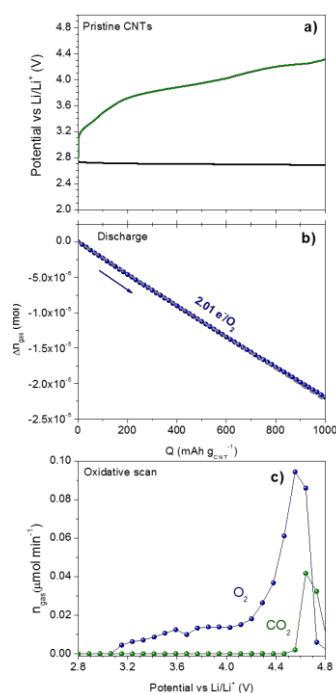

Tremendous research interest has been directed towards the non-aqueous lithium-oxygen (Li-O<sub>2</sub>) battery due to its high theoretical energy density (~3.5 kWh kg<sup>-1</sup>) with the potential to fully satisfy electric vehicle and grid leveling applications. The Li-O<sub>2</sub> battery chemistry consists of metallic Li and gaseous O<sub>2</sub> on the negative and positive electrodes respectively, giving a reversible overall reaction  $2\text{Li}^+ + \text{O}_2 + 2e^- \rightleftharpoons \text{Li}_2\text{O}_2$ , where solid Li<sub>2</sub>O<sub>2</sub> is the desired discharge product. To maximize this high energy density, it is paramount that stable, lightweight materials be used for the positive electrode. To this note, very few materials can compete with carbon due to its attractive properties including cost, relative abundance, weight, conductivity and porosity, all which are ideal properties for the positive electrode. However, it has been recently established that the use carbon can potentially exasperate chemical and electrochemical parasitic reactions occurring during discharge/recharge leading to the formation of insulating Li carboxylates and carbonates, all of which compromise the cycleability of the system.[1, 2] Therefore, it is of great interest to examine the characteristics of carbonaceous materials which can vary significantly with respect to synthesis procedures, defects, edges, and surface functional groups, all of which can greatly affect battery performance. Herein, we reveal the individual effects of defects and oxygen functional groups by systematically investigating their individual effects on carbon nanotubes (CNT) by *in-situ* on-line electrochemical mass spectrometry (OEMS) and extracted discharge/recharged CNT electrodes by *ex-situ* chemical analyses.

In this study, 4 different carbonaceous materials derived from commercial as-prepared CNTs were examined: (1) pristine, (2) o-functionalized, (3) defective, and lastly (4) graphitized CNTs. CNTs were used due to its well-defined structure, ease of surface modification and for the ability to fabricate binder-free positive electrodes. Oxygen functional groups were introduced onto the outer walls *via* chemical oxidation process. Defective CNTs were obtained by annealing o-functionalized CNTs in Ar (900°C) which removes the majority of o-functionalities. Graphitized CNTs were obtained through very high temperature annealing (2800°C). With these materials, binder-free, self-standing CNT electrodes were fabricated through a simple vacuum filtration process. Typical cell parameters involved 0.5M LiClO<sub>4</sub> in tetraglyme as the electrolyte with current density of 50 mA g<sup>-1</sup> (60 uA).

OEMS oxygen consumption measurements show that all 4 electrodes exhibit ~2 e<sup>-</sup>/O<sub>2</sub> during discharge suggesting prominent Li<sub>2</sub>O<sub>2</sub> formation, which is a contrast to recharge which shows e<sup>-</sup>/O<sub>2</sub> values that are significantly >2 e<sup>-</sup>/O<sub>2</sub> suggesting irreversibility and significant electrochemical parasitic reactions occurring during recharge. Figure 1 shows the pristine CNT (a) galvanostatic discharge/recharge curves, (b) corresponding discharge O<sub>2</sub> consumption, and (c) gas evolution from a linear sweep voltammogram after galvanostatic discharge to 1000 mAh g<sup>-1</sup>. Further details, results and discussion will be provided in the presentation.

# Improvements in the aqueous lithium-iodine battery

Georgios Nikiforidis, Hye Ryung Byon\*

Byon Initiative Research Unit (IRU), RIKEN, 2-1 Hirosawa, Wako, Saitama 351-0198, Japan  
georgios.nikiforidis@riken.jp, hrbyon@riken.jp

The novel aqueous lithium-iodine (Li-I<sub>2</sub>) battery has proven to be a cost-effective and high-performance energy storage technology that can be utilized in small (e.g. portable batteries) and large grid-scale (e.g. redox-flow battery, RFB) energy storage applications [1-2]. The significant advantage of this system is its energy storage capability of ~0.33 kWh kg<sup>-1</sup> attributed to the suitable operating potential (~3.5 V vs. Li/Li<sup>+</sup>) and high solubility of the I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple in the aqueous solution (~8.5 M in KI) as the catholyte. Besides, the operating potential of the I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple (0.536 V versus SHE) can avoid the electrolysis of water. The energy density can be further amplified by increasing the volume capacity of the aqueous catholyte since energy density is proportional to the concentration of I<sup>-</sup>/I<sub>3</sub><sup>-</sup> redox couple and the amount of solution. Previous studies on this system have reported current densities up to 12 mA cm<sup>-2</sup> could be applied with high storage capacity (~98% of the theoretical capacity), Coulombic efficiency (>99.5%) and cyclic performance (>99.5% capacity retention for 200 cycles) [1,3]. Yet, there is a lot of room for improvement. Subsequent studies have been focusing on two areas; 1) the improvement of the existing system through the enhancement of the electrochemical behavior of the I<sup>-</sup>/I<sub>3</sub><sup>-</sup> reaction (Fig. 1A) and 2) the development of a prototype Li-I<sub>2</sub> battery bearing solar cell. Regarding the first scope, catholyte without LiI yielded comparable performance to the cells containing LiI with regards to specific capacity and energy, voltaic and coulombic efficiencies as well as enhanced cycleability (>200 cycles) (Figs. 1B & C). Electrolytes containing only LiI/I<sub>2</sub> (without KI) showed enhanced specific capacity (by a factor of 3 but poor cycleability (due to the presence of Li)). Mixing of Pt with carbon replacing with (Pt-free) carbon current collectors produces slightly improved voltaic efficiencies (Fig. 1B) and more reversible behavior. Regarding, the new prototype system, it involves harvesting solar light by using hematite (α-Fe<sub>2</sub>O<sub>3</sub>) coated FTO photoanode for the I<sup>-</sup>/I<sub>3</sub><sup>-</sup> electrolyte. Preliminary results on the battery system under illumination show a great enhancement in the voltaic efficiency during charging (Fig. 1D).

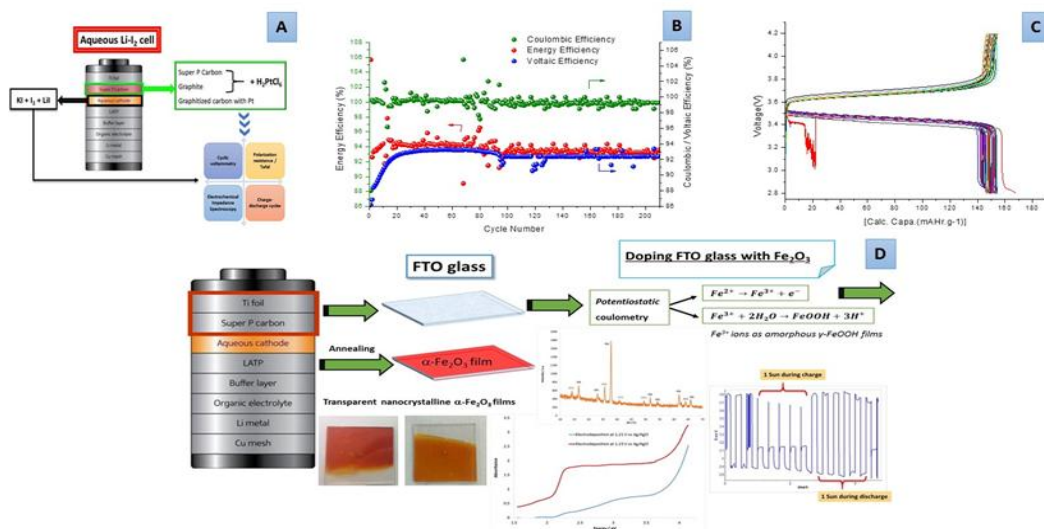

Figure 1: A) Schematic showing the investigation of the aqueous Li-I<sub>2</sub> cell. Electrochemical performance of Li-I<sub>2</sub> cell in 1.5 M KI and 0.3 M I<sub>2</sub> at a current rate of 1 mA cm<sup>-2</sup> B) Cyclic performance presenting Coulombic voltaic and energy efficiencies C) Two hundred cycled charge/discharge profile presenting specific capacity upon charge/discharge cycles D) Schematic showing process of doping FTO with α-Fe<sub>2</sub>O<sub>3</sub>, UV-Vis and XRD pattern of the α-Fe<sub>2</sub>O<sub>3</sub> FTO photoanode, charge/discharge behavior (t = 10 min) of the α-Fe<sub>2</sub>O<sub>3</sub> FTO photoanode based Li-I<sub>2</sub> cell under 1 SUN at a current rate of 1 mA cm<sup>-2</sup>. The catholyte is 1 M KI 0.03 M LiI 0.08 M I<sub>2</sub>.

Lithium air batteries are one of the most promising next generation secondary batteries that have extremely high specific energy density when compared to the conventional lithium ion batteries. The electrochemical processes in lithium air batteries include an electroreduction of oxygen at the cathode, thereby generating the oxygen species such as a superoxide anion in the cathode interface. Such an oxygen species is highly reactive to decompose the electrolytes and/or solvents in the electrolytic media, giving unfavorable decrease in the cycling performance of the battery cells.

On the other hand, room-temperature ionic liquids (RTILs), i.e. organic molten salts with melting points below ambient temperature, have received a great deal of attention as electrolytic media for various electrochemical systems due to the fact that RTILs have high electrochemical stability. Particularly, RTILs have been regarded as potential electrolytic media for lithium secondary batteries because of their stability and safety performances. From this point of view, we have designed a new class of phosphonium cation-based RTILs based on bis(trifluoromethylsulfonyl)amide (TFSA) anion as lithium battery electrolytes [1]. However, the application of the phosphonium RTILs to the electrolytes used in lithium air battery has been rarely reported. In this work, we present the electrochemical investigation of the oxygen reduction in the phosphonium RTILs (Fig. 1) as potential candidates for the lithium air battery electrolytes.

The preparation of phosphonium RTILs was carried out by aqueous ion exchange reactions of precursor phosphonium halides with Li-TFSA. The cyclic voltammetry and chronoamperometry measurements were carried out using a typical three-electrode cell consisting of a glassy carbon electrode as a working electrode, a Pt counter electrode and an Ag/Ag<sup>+</sup> reference electrode under oxygen atmosphere.

All phosphonium RTILs employed in this work showed the cathodic voltammetric response for the electrochemical oxygen reduction. It was found that the unsubstituted phosphonium RTILs (e.g. P<sub>2225</sub>-TFSA and P<sub>4441</sub>-TFSA) gave reversible cyclic voltammograms, whereas the introduction of substituents into phosphonium cations (e.g. P<sub>222(101)</sub>-TFSA and P<sub>222(3CN)</sub>-TFSA) tended to result in a decrease in the peak currents and/or reversibility. As shown in Fig. 2, P<sub>4441</sub>-TFSA exhibited relatively high peak currents with high reversibility in the voltammogram when compared to the corresponding ammonium RTIL. These results suggest that the unsubstituted phosphonium RTILs can be regarded as candidates for the air battery electrolytes.

Thermal analysis of Li-ion secondary cells is important for ensuring their safety and reliability. Recently, the use of Li-ion cells has been growing globally with a large number of cells powering a wide range of applications in variety of environments, and there have been several reported incidents raising safety concerns. Some of the cases have been related to overheating (thermal runaway) of Li-ion cells, leading to possible fire and explosion.<sup>1)</sup> In this work we analyze the thermal runaway behavior of 18650 Li-ion cells before and after storage and cycling degradation at high temperatures. The thermal behavior of the cells is analyzed using accelerating rate calorimetry. Non-self-heating, self-heating and thermal runaway regions of the cells as a function of state of charge and temperature are identified and compared among the cells.

Non-degraded and degraded commercial available 18650 Li-ion secondary cells were tested. The nominal capacity of the cells is 2550 mAh and the anode and cathode materials are graphite and LiCoO<sub>2</sub> + additives, respectively. In order to degrade the cells, these were stored at 80 °C and 100% SOC for one week. The cells were tested inside an accelerating rate calorimeter (ARC) 2000<sup>TM</sup> to record the thermal behavior and cell temperatures during the charge/discharge process. The cells were charged/discharged using a battery tester (KIKUSUI, PFX2011).

Figure 1 shows the self-heating rate before and after degradation of 18650 cells at 100% and 0% SOC. At 0% SOC, the cell after degradation (red) exhibits a higher self-heating rate than the cell before degradation (green), indicating that the cell becomes thermally unstable after degradation. On the other hand, at 100% SOC, the cell after degradation (blue) shows a lower self-heating rate than the cell before degradation (black), this is likely due to the reduce in capacity of the cell by the degradation. There is a difference of 380.9 mAh between the cells before and after degradation, it seems that this difference affects the thermal behavior of the cells when these are fully charged.

Fig. 1 Self-heating rate of 18650 Li-ion secondary cells before and after degradation at 0 and 100% SOC.

Tin-based material is an attractive choice for next generation high energy density lithium-ion battery (LIB) because of a good balance between electrochemical and mechanical properties, such as specific capacity, reaction potential, amount of volume change with lithiation and material density. Discharge capacity of more than 700 mAh g<sup>-1</sup> can be achieved readily. Even though the capacity is less than that of silicon, the volume expansion of Sn-based materials are smaller than that of Si-based materials, and is therefore easier to manage in a coated electrode. Among the different Sn-based material, metallic tin, with a bulk density of more than 7 g cm<sup>-3</sup>, has a theoretical capacity of 994 mAh g<sup>-1</sup> with high volumetric energy density. However, it suffers from poor cycle performance, partly due to the large number of phases transitions that the material undergoes with lithiation.<sup>1</sup> In addition, melting point of tin is only about 230°C, limiting the processibility of the material and also increasing the chance of cold welding during charge-discharge. Tin oxides such as SnO and SnO<sub>2</sub> have also been highly researched as anode materials for LIB. The presence of oxygen suppresses the phase transitions of Sn-Li, raises the melting temperature of the material, reduces the amount of volume expansion during lithiation and increases the cycle stability of the material.<sup>2</sup> During initial discharging, the materials undergo a conversion reaction to form Li<sub>2</sub>O, followed by alloying of Sn and Li.<sup>2,3</sup> Most research papers limit the charge potential to about 1V (utilization of only the Sn-Li alloy reaction), but the first cycle efficiency is less than 40%, meaning that in a full cell configuration, excess cathode has to be used to overcome the lithium lost during the first cycle. First cycle efficiency and energy density can be improved further by raising the charge potential to utilize the Li-O reaction, but it often results in fast capacity drop.<sup>3-6</sup>

In this study, we stabilize both the conversion and alloy reactions of nano-SnO<sub>2</sub> in a stretchable polyimide (PI) matrix. The nanoparticles allow efficient lithium storage and the PI matrix keeps the integrity of the secondary particles by buffering the volume change and preventing material loss during charge and discharge. Even with sodium carboxymethyl cellulose as the binder in the electrode, a capacity of more than 700 mAh g<sup>-1</sup> remains after 50 cycles for the SnO<sub>2</sub>-PI matrix samples when cycled between 0.01 and 2.5 V. Capacity retention is 97% after 100 cycles, as opposed to 80% without PI matrix (as shown in Fig. 1). Detailed work to study the effect of the amount of PI and polymerization conditions on electrochemical performance is underway and the charge-discharge mechanism will be discussed at the meeting. By utilizing both the conversion and alloy reactions of SnO<sub>2</sub>, first cycle efficiency is improved to more than 60% and capacity is increased by 51.8% compared to just using the Sn-Li alloy reaction.

Figure 1. Cycling performance of SnO<sub>2</sub> (diamond) and SnO<sub>2</sub>-PI matrix (square) between 0.01 and 2.5V with a current of 250 mA g<sup>-1</sup>. Both samples were initiated for 5 cycles at 100 mA g<sup>-1</sup> before the cycling test.

s-okada@cm.kyushu-u.ac.jp

Electrolytes have essential effect on the electrochemical properties and thermal stability of batteries. For Li-ion batteries, organic solvent-based electrolytes have been widely applied in practical application. Many studies had been carried out on the electrolytes to investigate their characteristics and to improve battery performances. Recently ambient temperature sodium-ion batteries have drawn interest as a power source for large-scale grid energy storage due to the low cost and abundant resources of sodium. Na is located below Li in the periodic table and they share similar chemical properties in many aspects. The fundamental principles of the Na-ion batteries and Li-ion batteries are identical. Therefore, much of new components for Na-ion batteries could be developed according to their counterparts for Li-ion batteries and the electrolytes are no exception. Kinds of Na salt-containing organic solvent-based electrolyte have been successfully used in investigation of various Na-ion batteries. However, unlike that done for the electrolytes of Li-ion batteries, few studies have been performed on the electrolytes of Na-ion batteries [1-4], especially about their thermal characteristics. In the present work, kinds of NaClO<sub>4</sub> or NaPF<sub>6</sub>-containing organic solvent-based electrolytes were studied by a thermogravimetry-differential scanning calorimeter (TG-DSC). By comparing the Na-salt electrolytes to their Li-salt counterparts, the thermal stability of the electrolytes of Na-ion batteries were evaluated. At the same, the mechanisms of electrolyte thermal decomposition were also discussed.

The organic solvents and electrolytes in the present work were commercially available or self-prepared. The temperature profiles of 1-3  $\mu$ l test electrolyte in a hydraulic-sealed stainless steel pan were carried out by the TG-DSC system. During measurement, the TG signal was monitored simultaneously to confirm that there was no leakage.

Figure 1 shows the DSC curves of 1, 2 and 3  $\mu$ l 1 M NaClO<sub>4</sub>/PC and 1 M LiClO<sub>4</sub>/PC sole electrolytes. Both kinds of electrolytes gave exothermic heat at around 300°C due to the thermal decomposition of the electrolytes. However, the exothermic peaks were obviously different, including peak shape, peak position and peak intensity. This phenomenon indicated that these two kinds of electrolytes had completely different thermal decomposition mechanism only because of the different cations of the salts. Similar comparisons were also carried out on other kinds of electrolytes. Detailed discussion will be presented in the meeting.

# Application of ionic liquid electrolytes to Si electrode as a Li-ion battery anode

Masahiro Shimizu, Hiroyuki Usui, and Hiroki Sakaguchi\*

Department of Chemistry and Biotechnology, Graduate School of Engineering, Tottori University  
4-101 Minami, Koyama-cho, Tottori 680-8552, Japan  
sakaguch@chem.tottori-u.ac.jp

Li-ion batteries are one of the most popular energy storage devices due to their high energy densities. In the light of application for large-scale systems such as power supply for electric vehicles and stationary battery, a further increase in its energy density has been required. Silicon is a promising anode material replacing the currently used graphite due to its high theoretical capacity of  $3580 \text{ mA h g}^{-1}$  ( $\text{Li}_{15}\text{Si}_4$ ). There is, however, the critical issue that Si undergoes severe volume expansion and contraction during alloying and dealloying reactions with Li. The volumetric changes ratio per Si atom from Si to  $\text{Li}_{15}\text{Si}_4$  correspond to 380%, which results in the generation of high stresses and large strains in the active material. The strains accumulated by repeated charge–discharge cycling cause disintegration of the Si electrode leading to a rapid capacity fading. On the other hand, an electrolyte is one of the key factors determining the battery performance. Room temperature ionic liquids have received much attentions as an alternative to a conventional organic electrolyte consisting of carbonate-based solvents because of their excellent physicochemical properties of high thermal stability, negligible vapor pressure, and wide electrochemical window. We demonstrated that the cycle stability of the Si electrode is remarkably improved by using the ionic liquid of 1-((2-methoxyethoxy)methyl)-1-methylpiperidinium bis(trifluoromethylsulfonyl) amide (PP1MEM-TFSA). An ether functional group in the PP1MEM cation reduces an interaction between Li ion and TFSA anion compared to the piperidinium-based ionic liquid with the cation having an alkyl side chain, which can promote Li-insertion into the Si electrode, and increase its reversible capacity. PP1MEM-TFSA delivered a comparatively high capacity of  $1050 \text{ mA h g}^{-1}$  even at the 100th cycle, whereas the capacity in an organic electrolyte of 1.0 M LiTFSA-dissolved in propylene carbonate (PC) drastically decreased to  $110 \text{ mA h g}^{-1}$  (Fig. 1). In this study, we investigated the origin of the improved cycling performance of Si electrodes in the ionic liquid electrolyte by analyzing the deterioration mechanisms for Si electrodes in organic and ionic-liquid electrolytes from the viewpoint of the Li-insertion distributions.

Raman spectroscopy is a powerful tool for identifying the crystallinity of an active material. Crystalline Si (c-Si) electrochemically reacts with Li to form c- $\text{Li}_{15}\text{Si}_4$  phase at room temperature. The c-Si then undergoes amorphization after the Li-extraction process to transform into amorphous Si (a-Si), when the band position of  $520 \text{ cm}^{-1}$  in a Raman spectrum showing c-Si typically shifts to  $490 \text{ cm}^{-1}$  indicating a-Si. By taking advantage of this nature obtained by the Raman scattering, Si that reacted with Li can be distinguished from unreacted Si. It was revealed that, in the case of using PC, crystalline Si locally remained in the electrode after cycling, and Li–Si alloying and dealloying reactions occurred in limited regions. This leads to the generation of intensive stress accumulation due to the extreme volume changes of Si in the regions inside the electrode, causing severe disintegration of the Si electrode. Consequently, the anode property of the Si electrode in PC resulted in the very poor performance. In contrast to the organic electrolyte, Li–Si reactions uniformly took place over the entire electrode in PP1MEM-TFSA, which relatively avoided any stress accumulation leading to its disintegration. This is considered to be the reason why the cycle performance of the Si electrode was significantly improved by using the ionic liquid instead of the conventional electrolytes [1].

Fig. 1 Dependence of discharge (Li-extraction) capacities and coulombic efficiencies on cycle number for Si electrodes in the electrolytes using PC (organic solvent) and PP1MEM-TFSA (ionic liquid).

Electrochemical energy storage is receiving much attention because of the strong industrial and social demands for their widespread use in the smart grid. However, high-energy batteries utilizing ion (de)intercalation electrodes are not satisfactory for high-power applications, while high-power electrochemical capacitors generally have low energy density. This trade-off between the power and energy densities intrinsically originates from the charge storage mechanism of the electrodes: ion (de)intercalation stores charge more slowly than a double layer, whereas a double layer stores less charge than ion (de)intercalation. Therefore, the pseudocapacitance (or redox capacitance) has become an increasingly important mechanism for charge storage, where the energy and power densities are partially liberated from the trade-off.

We have targeted a novel family of nanosheet compounds, MXenes, as potential pseudocapacitor electrodes for lithium-ion and sodium-ion batteries. MXenes are chemically derived from layered  $M_{n+1}AX_n$  or MAX phases (M: early transition metal, A: A-group element, and X: C and/or N) [1,2]. As the MXene has both a high electrical conductivity and large surface area, its application to pseudocapacitor electrodes holds great promise [3,4]. In this presentation, we report on  $Ti_{n+1}C_nT_x$  ( $n = 1, 2$ ) as negative electrode materials for lithium-ion and sodium-ion batteries.  $Ti_{n+1}C_nT_x$  consists of abundant and low-cost elements, enabling fabrication of sustainable energy sources. The pseudocapacitance of  $Ti_{n+1}C_nT_x$  allows batteries to be liberated from the trade-off between high energy and high power [5].

$Ti_2CT_x$  and  $Ti_3C_2T_x$  were synthesized by treating the MAX phases  $Ti_2AlC$  and  $Ti_3AlC_2$  with a HF aqueous solution. The charge-discharge experiments revealed that both MXenes deliver a large reversible capacity. For example, Figure 1 shows the charge-discharge curves of  $Ti_2CT_x$  measured between the cut-off voltages of 0.1–3.0 V versus  $Na/Na^+$  at 20 mA/g. After the initial few cycles,  $Ti_2CT_x$  exhibits stable and efficient electrode performance. The charge/discharge profiles exhibit a capacitor-type slope in the range of 0.1–2.3 V (an average operating potential of 1.3 V), delivering a reversible capacity of approximately 175 mAh/g with good cycle stability (12% and 19% losses of the second capacity after 50 and 100 cycles, respectively).

Detailed reaction mechanism of MXene nanosheets will be discussed on the basis of ex situ XRD, X-ray absorption spectroscopy, and solid state  $^{23}Na$  magic angle spinning NMR.

# ***In-situ* XRD of High Voltage Lithium Insertion Electrodes**

Michael G. Palmer, Andrew Hector, John Owen  
University Of Southampton  
School of Chemistry, University of Southampton, Hampshire, SO17 1BJ  
M.Palmer@soton.ac.uk

High voltage lithium-ion electrodes have recently been suggested for application in high energy density batteries for electric vehicles. Olivine structured lithium metal phosphates are a group of positive electrode materials, of which the best developed phase,  $\text{LiFePO}_4$ , is now commercially available and used in applications from power tools to electric vehicles.<sup>1</sup> The isostructural  $\text{LiCoPO}_4$ <sup>2</sup> can operate at higher potentials but is less used due to poor conductivity and cycling behavior.

This work looks at optimizing the  $\text{LiCoPO}_4$  electrode, in terms of carbon coated loading, particle shape and morphology. *In-Situ* XRD was carried out to examine changes in phase behavior during cycling using a cell designed in house<sup>3</sup>. The cell contained an aluminum foil current collector that also acted as the X-ray window. Domed lithium was used as the negative electrode to allow for an even pressure to be applied across the diameter of the stack, countering the effect of deformation of the aluminum window under pressure and allowing a similar electrochemical performance to be achieved to that observed in a standard Swagelok cell.

**Figure 1** (a) Schematic and (b) image of the electrochemical cell used in the *in situ* XRD studies.

*Ex-situ* XANES data were collected on cycled electrodes to observe the changes in oxidation state of cobalt across the bulk of the electrode and to investigate the origins of the strong dependence of cycling performance on the atmosphere and thermal conditions used in the material synthesis.

Silicon as a negative electrode material for lithium-ion batteries has substantially higher capacity than conventional graphite electrode, but suffers from problems such as low coulombic efficiency and poor capacity.<sup>1-4</sup> In this study, fluoroethylene carbonate (FEC) was used as electrolyte additive for commercialized LP40 (1 M LiPF<sub>6</sub>, ethylene carbonate (EC) : diethyl carbonate (DEC) = 1:1) electrolyte and significantly improved cyclability of silicon-based electrode. The solid electrolyte interphase (SEI) formed from the decomposition of ethylene carbonate (EC) and diethyl carbonate (DEC), without the FEC additive present, was observed to cover surface voids and lead to an increase in polarization. However, with the presence of FEC, which degrades at a higher reduction potential than EC and DEC, instantaneously a conformal SEI was formed on the silicon electrode as shown in figure 1. The decomposition of the FEC additive was investigated by synchrotron-based X-ray photoelectron spectroscopy (PES) giving a chemical composition depth-profile. The reduction products of FEC were found to mainly consist of LiF and -CHF-OCO<sub>2</sub>- type compounds. This stable SEI layer sufficiently limited the emergence of large cracks and preserved the original surface morphology as well as suppressed the additional SEI formation from the other solvent. Moreover, FEC influenced the lithium salt LiPF<sub>6</sub> decomposition reaction and may have suppressed further salt degradation. This study highlights the vital importance of how the chemical composition and morphology of the SEI influence battery performance.

Figure 1. Schematic representation of the SEI formation on silicon anode which is long-time cycled with different electrolytes FEC/LP40 (a) and LP40 (b), respectively. The two SEI layers are different in compositions and highlighted with different colors.

# Semi-solid flow battery: an emerging electrochemical system

Edgar Ventosa,<sup>a</sup> Cristina Flox,<sup>b</sup> Joan Ramon Morante,<sup>b</sup> and Wolfgang Schuhmann<sup>a</sup>

<sup>a</sup> *Analytische Chemie – Center for Electrochemical Sciences (CES), Ruhr-Universität Bochum, Universitätstr. 150, D-44780 Bochum, Germany.*

edgar.ventosa@rub.de*

Redox flow batteries (RFB) are promising technologies for energy storage due to the long life, low cost, high round-trip efficiency and independent scalability of energy and power capabilities. Semi-solid flow batteries (SSFBs) are a special class of RFB, in which anolyte and catholyte consist of flowable suspensions of solid active materials rather than dissolved redox species. Thus, the concentration of active redox centres in the anolyte and catholyte of the SSFB can be significantly increased.<sup>1</sup> Using intercalation type active materials such as those typically used in Li-ion batteries (LIBs), e.g.  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ ,  $\text{LiCoO}_2$  or  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$ , the energy densities can reach up to  $300\text{--}500\text{ W h L}^{-1}$ , which is more than 10 times higher than that of all-vanadium RFBs ( $40\text{ W h L}^{-1}$ ). Compared to LIBs, SSFBs present several advantages: (I) power and energy can be scaled independently, (II) the amount of inactive materials such as current collectors or housing is decreased, and (III) the manufacturing processes become simpler and more cost-effective.

Since SSFBs deploy Li-ion or Na-ion host materials, SSFBs and classic solid electrode batteries share the same chemistry. However, the replacement of solid electrodes of classic ion batteries by the fluid electrodes employed in semi-solid flow batteries brings new electrochemical challenges. After revising the fundamentals of the operating principles of SSFBs, two particular new challenges are presented and discussed: i) the critical influence of the electrical conductivity of the active materials,<sup>2</sup> and ii) the new role of the solid electrolyte interphase (SEI).<sup>3,4</sup> In the first case, the weaker electrical conductivity of fluid electrodes allows ionic and electric phenomena to be easily differentiated, which is used to study the electric charge/discharge mechanisms of battery materials. In the second case, the SEI changes from ionic to electron barrier, for classic solid electrode batteries and SSFBs, respectively, and results in different limitations.

Lithium-sulfur (Li-S) batteries are considered to be one of the most promising energy storage devices in next generation high energy power system, owing to their high specific capacity ( $1675 \text{ mAh g}^{-1}$ ) and energy density ( $2600 \text{ Wh kg}^{-1}$ ).<sup>1-3</sup> However, the insulation of sulfur and high solubility of lithium polysulfide in the organic electrolyte lead to the low utilization of active materials and the poor cycling performances, which seriously impede the rapid development of Li-S batteries.<sup>4-6</sup>

In this work, we discover that a multifunctional carbon nanotube paper/titanium dioxide barrier can effectively reduce the loss of active materials and suppress the diffusion of lithium polysulfide to the anode (**Figure 1**), thereby improving the cycling stability of lithium-sulfur batteries. Moreover, we investigate the special interactions between  $\text{TiO}_2$  and sulfur species with scanning transmission electronic microscope (STEM), X-ray photoelectron spectroscopy (XPS), Raman spectra, and the density functional theory (DFT) calculation. Results of these studies will be presented and discussed.

**Figure 1.** (a) Illustration for the special construction of Li-S batteries. (b) Scanning electron microscopy (SEM) image of CNTP/ $\text{TiO}_2$  cross-section. (c, d) The representative geometries of the  $\text{Li}_2\text{S}_4$  molecules on rutile  $\text{TiO}_2$  (110) surface.

**Abstract:** High-energy-density 0.5Li<sub>2</sub>MnO<sub>3</sub>–0.5Li(Mn<sub>0.375</sub>Ni<sub>0.375</sub>Co<sub>0.25</sub>)O<sub>2</sub> composite cathodes for lithium rechargeable batteries are synthesized using an auto-combustion method. The electrode charge-discharge properties are studied at 25°C and 50°C in Li<sup>+</sup>-containing N-butyl-N-methylpyrrolidinium bis(trifluoromethanesulfonyl)imide (BMP-TFSI) and N-propyl-N-methylpyrrolidinium bis(trifluoromethanesulfonyl)imide (PMP-TFSI) ionic liquid (IL) electrolytes. The IL electrolytes possess high decomposition temperature (~400 °C) and thus they are ideal for high-safety applications. As compared to Li<sup>+</sup>/BMP-TFSI IL, Li<sup>+</sup>/PMP-TFSI IL exhibits higher ionic conductivity and lower viscosity. As a result, the composite cathode exhibits comparatively superior electrochemical performance in Li<sup>+</sup>/PMP-TFSI IL electrolyte. With an increase in cell temperature from 25 to 50 °C, the maximum capacities and rate capabilities of both IL cells are significantly improved. The discharge capacities of 304 mAhg<sup>-1</sup> (@10 mA g<sup>-1</sup>) and 223 mAhg<sup>-1</sup> (@100 mA g<sup>-1</sup>) are obtained at 50 °C for the Li<sup>+</sup>/PMP-TFSI cell, which are superior to those for a control cell with a conventional organic electrolyte. We have reported that at elevated temperature the cyclability of the composite cathode is markedly improved when the IL electrolytes (rather than a conventional organic electrolyte) are used. We also performed immersion tests to evaluate the electrode deterioration and post mortem characterizations by SEM and XRD to explain the improved performance of 0.5Li<sub>2</sub>MnO<sub>3</sub>–0.5Li(Mn<sub>0.375</sub>Ni<sub>0.375</sub>Co<sub>0.25</sub>)O<sub>2</sub> in IL electrolytes. The pyrrolidinium based IL electrolytes can be used as safe electrolytes for lithium-ion batteries with the Li-rich rich composite cathode.

# New Concept Aqueous Rechargeable Batteries with High Energy Densities

Yuping Wu<sup>1,2,\*</sup>, Zheng Chang<sup>2</sup>, Yanfang Wang<sup>2</sup>

*College of Energy, Nanjing Tech University, Nanjing 211816, Jiangsu Province, China  
New Energy and Materials Laboratory (NEML), Department of Chemistry & Shanghai Key Laboratory

e-mail: wuyp@njtech.edu.cn, wuyp@fudan.edu.cn*

Batteries is originally from aqueous solution. To further increase their energy densities, one revolutionary example of rechargeable batteries is the birth of lithium ion batteries in the early 1990s. However, the safety from the combustible organic electrolytes is a serious and challenging problem in the case of large-scale applications such as energy storage in smart grids. As a result, it comes back to aqueous electrolyte again to search for a solution. The aqueous solution should be neutral and green, and one example is aqueous rechargeable lithium batteries (ARLBs) and aqueous rechargeable sodium batteries (ARSBs) [1-3]. Recently, the energy density is markedly improved in comparison with that for lithium ion batteries due to the “cross-over” effect instead of the traditional overpotentials [4]. This effect will bring unpredicted promise for the new power sources since it can markedly increase the output voltage of aqueous batteries to above 3 V, much higher than the theoretical stable window of water, 1.23 V. The estimated practical energy density will be much higher than those for lithium ion batteries. For example, the estimated practical energy densities for 2nd and 3rd generations ARLBs will be 170-230 and > 400 Wh/kg [4-6]. This opens new choices for smart grids and electric vehicles as a chemistry of post lithium ion batteries.

Lithium sulfur (Li/S) battery is an attractive electrochemical energy storage system with a high theoretical specific capacity of 1672 mAh g<sup>-1</sup> and a theoretical energy density of 2600 Wh kg<sup>-1</sup> [1]. Sulphur is a promising active material also because of its abundance, low-cost and environmentally friendliness when compared with certain toxic transition-metal compounds.

However, practical application of Li/S batteries is hindered by several drawbacks as: the electrical-insulating nature of sulfur results in its low utilization; lithium polysulfides intermediate products of electrochemical process are easily soluble into the organic electrolytes, which leads to severe capacity fading and low coulombic efficiency.

Numerous attempts have been made to overcome these disadvantages by mixing sulfur with conducting agents such as conducting carbon materials and/or conductive polymers [2-3]. In result the utilization of sulfur and capacity per the unit mass of sulfur have been improved by these methods. Carbon nanotubes (CNTs) have been extensively studied as conductive matrix to load sulfur due to their large specific surface area and abundant active sites [4]. Though more open porous structures formed by CNTs greatly improved electrolyte infiltration. However, the addition of a large amount of conducting agent and binder results in the lower practical capacity per the unit mass of cathode composite. Furthermore, conventional electrodes for lithium-ion batteries need current collectors, such as metal foils, resulting in even lower available gravimetric capacity of electrode.

In current work a novel sulfur/polyacrylonitrile/multiwalled carbon nanotube ternary composite electrode (S/PAN/MWCNT) without binder and current collector was prepared by simple technique and examined as a cathode for Li/S battery (Fig. 1). The partially pyrolyzed and cyclized PAN can stabilize sulfur and suppress the sulfur dissolution into electrolyte solutions through the redistribution of electrons in the outermost electronic orbitals of sulfur or through forming chemical bonds between PAN and sulfur, because of polarized C-N chemical bonds.

Formation of a homogeneous hierarchical mesoporous structure was observed by SEM, EDS mapping and XRD techniques. The lithium cell with this ternary composite cathode delivered a discharge capacity of 489 mAh per gram of cathode (1450 mAh g<sup>-1</sup> S) in the second cycle at 0.2 C, and retained about 85% of this value over 200 cycles. Even up to 2 C rate, the lithium cell demonstrated an excellent rate capability, delivering a highly reversible discharge capacity of 950 mAh g<sup>-1</sup>.

Fig 1. Schematic of the S/PAN/MWCNT binder free cathode preparation and it's cycleability at 0.2 C.

Department of Applied Chemistry, Xi'an Jiaotong University, Xi'an, China, 710049

Email: dingsj@mail.xjtu.edu.cn

Herein, we report some facile and general methods to directly grow metal oxide ( $\text{TiO}_2$ ,  $\text{SnO}_2$ ,  $\text{NiO}$ ,  $\text{Co}_3\text{O}_4$  and  $\text{NiCo}_2\text{O}_4$ ) or metal sulfide ( $\text{MoS}_2$ ) nanosheets on sulfonated polystyrene spheres, modified CNTs or graphene oxide. After calcinations in air or inert atmosphere, these materials were converted into metal oxides hollow spheres assembled from nanosheets and metal oxides nanosheets@carbon (amorphous, graphene and CNTs) materials. Due to the porous structure (derived from the pile of nanosheets) and internal voids, these metal oxide nanosheets can store more lithium ions, have more fast lithium ions transfer rate and thus exhibit improved lithium storage capability. The graphene and CNTs support serves as a highly conductive substrate that is beneficial to the better lithium ions storage performance.

In order to develop a battery with the large capacity and the long life cycle for the electric vehicles and the mobile devices, Li-rich layered oxides have been proposed and widely investigated.  $\text{Li}_2\text{MnO}_3$  was known to be electrochemically inactive in the past studies. However, the recent researches have proven that it could be electrochemically active under the higher cell voltage. In this perspective,  $\text{Li}_2\text{MnO}_3$  is being newly focused as the great potential candidate and it also contains a large number of lithium ions compared to other conventional cathode materials such as  $\text{LiCoO}_2$ . Recently, many experimental and theoretical studies reported that the oxygen atom rather than the manganese plays an important role in the operation of the battery. However, the fundamental role of oxygen during the charge-discharge cycle has not been fully understood. In this talk, we will present our recent findings using theoretical calculations based on the density functional theory as well as the experimental measurements of the characteristics of cell charge-discharge behavior and *in situ* XANES spectroscopy. More specifically, following understandings will be mainly discussed. (1) Oxygen atoms in the transition metal layer mainly participate in the charge compensation process for the electrochemical activity of  $\text{Li}_2\text{MnO}_3$ . (2) Oxygen atom can be released at the very early stage of the charge cycle and this leads to the cell voltage drop. (3) During delithiation process, the oxygen-loss is accelerated and the oxygen released structure becomes more energetically stable. (4) The reduced intensity and the shift of the XANES spectra are originated from the oxygen-loss phenomena.

# Electrochemical Stiffness in Lithium Ion Batteries

Andrew A. Gewirth, Hadi Tavassol, Elizabeth M. C. Jones, Nancy R. Sottos  
University of Illinois  
600 S. Mathews Avenue, Urbana, IL 61801 USA  
agewirth@illinois.edu

Higher power and charging rates are essential for large scale adoption of lithium-ion batteries in transportation applications. While lithium-ion batteries are ubiquitous in portable electronics, their performance and lifetime suffer during high rate charging and high power discharging. In such extreme electrochemical conditions, the mechanical response of electrode materials governs their degradation behavior. Here, we present a new technique to probe the electrochemically-induced mechanics of electrodes by calculating the electrochemical stiffness of electrodes via coordinated *in situ* stress and strain measurements. Through the electrochemical stiffness, we elucidate inherent and rate-dependent mechanical responses of graphitic battery electrodes. We find that stress and strain are asynchronous as shown in the figure. In particular, stress development is found to lead strain development as different graphite-lithium intercalation compounds are formed. Additionally, our analysis reveals inversely scaled rate-dependent behaviors for stress and strain responses. Stress scales as scan rate while strain scales with charge (or, equivalently, capacity). These measurements provide a new paradigm for understanding mechanical effects in intercalation systems, such as batteries. Stress arises as resistance to lithiation, while strain arises as a consequence of lithiation. Electrochemical stiffness measurements provide new insights into the origin of the rate-dependent chemo-mechanical degradations, and provide a probe to evaluate advanced battery electrodes.

# Forward and reverse differential-pulse applied in the formation of solid electrolyte interface with constant temperature addition in lithium ion battery

The solid electrolyte interface (SEI) is a chemical-formed membrane, which has good ion conductivity and electron insulation as well as a protection layer that prevents the exfoliation of graphite in redox process. Normally, the first cycle in commercial protocol uses a constant current and constant voltage method (CC-CV), and this process creates a highly porous and polarized SEI, which degrades the performance of Li ions battery [1]. In our previous result, the forward and reverse differential-pulse method (FRDP) is studied to improve the characteristics of SEI [2]. In this study, the SEI formation adds a constant temperature in combined with FRDP.

The constant temperature-FRDP mechanism (CT-FRDP) is investigated in two kinds of electrolytes, EC/EMC and EC/PC/DEC at the temperatures of 25 and 40°C. All of the battery samples are charged and cycled at a high rate and a high temperature in order to examine the performance. In addition, the electrode's surface is also observed by scanning electron microscopy, electrochemical impedance spectroscopy, X-ray photoelectron spectroscopy, and Li ion kinetics analysis.

The results indicate that a unique species is found and furnishes a temporary redox behavior only during the CT-FRDP process. This unique species sensitively works on anode's surface and enhances the formation of SEI. We believe that temporary redox behavior creates a new reaction mechanism of SEI and this reaction pathway displays a crucial route for battery application.

The steadily increasing demand for high-energy storage devices for portable consumer electronics as well as for large-scale applications as, for instance, electric vehicles, propels the battery research forward. Nowadays, lithium-ion batteries are the state-of-the-art energy storage device due to their high energy, power density and efficiency, as well as long durability [1]. However, especially for large-scale applications the energy density of commercial batteries is still insufficient. Thus, the utilization of new active materials with higher specific capacity than the currently used anode and cathode materials might enable an improved energy density [1]. Accordingly, instead of insertion or intercalation anode materials alternative higher specific capacity anode materials reversibly storing lithium by an alloying or conversion process are intensively investigated. Herein, we present our studies on anode materials based on mixed conversion/alloying lithium-ion storage mechanism, which are ideally characterized by low (de-)lithiation potential, high coulombic efficiency and long-term cycling stability. In order to gain deeper insights into the crystal structure of the synthesised samples and into the mixed conversion/alloying lithium storage mechanism of this rather new class of materials various characterisation method as, for instance, X-ray diffraction, X-ray photoelectron spectroscopy, X-ray absorption spectroscopy, scanning electron microscopy and electrochemical techniques were employed.

In Fig. 1 the galvanostatic cycling tests for two anode materials from the class of transition metal-doped metal oxides are presented. Both materials show a highly stable cycling behaviour with an extraordinary high specific capacity compared to the conventionally utilised anode material graphite ( $372 \text{ mAh g}^{-1}$ ). The specific capacity of Fe-doped ZnO is about  $1100 \text{ mAh g}^{-1}$  after 60 cycles. Fe-doped SnO<sub>2</sub> reaches a reversible specific capacity of more than  $1500 \text{ mAh g}^{-1}$  after 10 cycles.

By means of our studies, we were able to elucidate the crystal structure and to propose a lithium storage mechanism for Fe-doped oxides. The family of transition metal-doped metal oxides show a great potential as high capacity anode material for application in lithium-ion batteries. Moreover, our recent studies demonstrate the potential of utilizing mixed alloying/conversion lithium storage materials in practical applications.

# In-situ Raman Spectroscopy and EQCM study of Lithium-Sulfur Batteries

Heng-Liang Wu, Laura A. Huff and Andrew A. Gewirth  
 Department of Chemistry, University of Illinois at Urbana-Champaign,  
 600 S. Mathews Avenue, Urbana, IL 61801 USA.  
 notcool@illinois.edu

In this talk, in-situ Raman spectroscopy and electrochemical quartz crystal microbalance (EQCM) measurements were used to investigate the mechanism of sulfur reduction in lithium-sulfur battery slurry cathodes. Raman spectroscopy shows that long chain polysulfides ( $S_8^{2-}$ ) were formed via  $S_8$  ring opening in the first reduction process at  $\sim 2.4$  V vs  $Li/Li^+$  and short chain polysulfides such as  $S_4^{2-}$ ,  $S_4^-$ ,  $S_3^{2-}$  and  $S_2O_4^{2-}$  were observed with continued discharge at  $\sim 2.3$  V vs  $Li/Li^+$  in the second reduction process. These polysulfides are all reversible during charge process. Elemental sulfur can be reformed in the end of the charge process. (1-4)

Rate constants obtained for the appearance and disappearance polysulfide species show that short chain polysulfides are directly formed from  $S_8$  decomposition. The rate constants for  $S_8$  reappearance and polysulfide disappearance on charge were likewise similar, suggesting that polysulfide oxidation and reduction is quasi-reversible. The formation rate of polysulfide species depends on the potential. The rate obtained at 1.5V is three times larger than 2.2 V, suggesting the larger driving force in the decomposition  $S_8$  and the formation of short chain polysulfides. The formation of polysulfide mixtures at partial discharge was quite stable for at least 2hr. We also examined the effect of  $CS_2$  addition on the sulfur reduction mechanism. Electrochemical and Raman results show that  $CS_2$  stabilizes the  $S_8^{2-}$  product and inhibits further discharge of the cell.

In-situ EQCM results show that the sulfur-carbon cathode gains Sauerbray-mass during the first discharge plateau. The crystal resistance ( $R_c$ ) was used to monitor the viscosity ( $\eta_L$ ) and density ( $\rho_L$ ) of the polysulfides in contact with electrode as well as the change of electrode surface. (5) The change in  $R_c$  after first discharge plateau suggests that the Sauerbray equation is no longer valid and that the porosity of sulfur-carbon cathode increases particularly in the lower potential region (e.g. 1.5 V). The battery performance results also show the more stable capacity in the cycling region between 3.2 V to 1.8 V relative to 3.2 V to 1.5 V. Finally, we also report that new additives in Li-S batteries both stabilize polysulfides and contribute to better cycling performance.

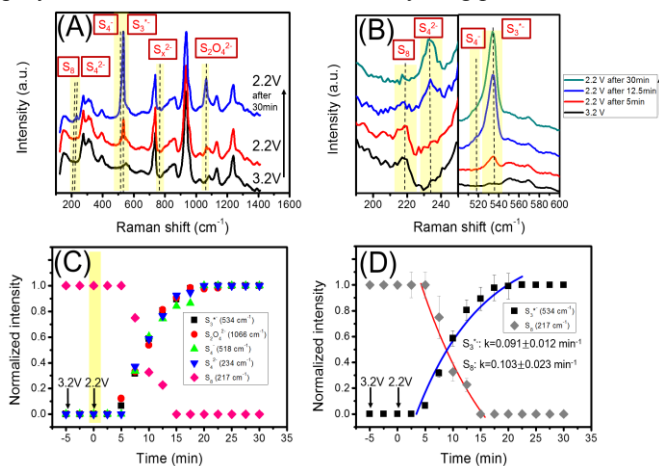

Figure 1(A-B) In-situ Raman spectra of the sulfur-carbon cathode obtained at partial discharge (C-D) The normalized intensity of sulfur species were plotted as a function of time and fit to extract a rate (k).

# Explore the Failure Mechanism in Lithium-ion Batteries by Forensic Analysis Techniques

Alvin Wu, Dean Wu, Carl Wang; Ph. D.  
Underwriters Laboratories Taiwan Co., Ltd.  
1/F, 260, Da-Yeh Road, Peitou, Taipei City, Taiwan 112  
[Alvin.Wu@ul.com](mailto:Alvin.Wu@ul.com)

In the investigation of field incidents involve with lithium-ion batteries, it is always critical to understand the root cause so the safety issues can be identified and improved. However, in reality, finding the root cause and failure mechanism of failed lithium-ion batteries is a big challenge due to two reasons. First of all, the battery may be burned or destroyed so it is hard to find any significant evidence. Secondary, there are usually multiple contributing factors come together to result in catastrophic failure in a battery, so it is not easy to have a solid conclusion of the real cause of the incident.

In order to address this complicated situation, this study proposes a method with a series of forensic analysis techniques is to explore all potential root causes that could arise from issues in battery design, quality and aging effects [1] [2]. A typical process to identify the potential paths of a battery failure event is given in Figure 1 below. To analyze the possible root causes, all of the detailed background information, such as the environmental conditions, system operation status while failure occurs and all data recorded by the battery management system will need to be collected as the basis to logistically develop the basic hypothesis. To check the validity of the assumptions, a forensic analysis approach will be the best way to directly find out scientific evidences. Furthermore, the simulation of all conditions to repeat the field event will sometimes be helpful to achieve a more solid conclusion regarding the failure mechanisms behind the battery incident. A good example of investigation project using the forensic analysis techniques to study the battery field event is the Boeing 787 battery incident in January 2013 at Logan International Airport [3]. The cell design was investigated thoroughly by reverse engineering, analytical techniques, non-destructive and destructive analysis, and simulation of abuse conditions to correlate well between the root causes and safety behaviors under various operating conditions, hence the root cause to the field event can be successfully identified with specific evidences provided.

Figure 1. Typical Process to Identify the Root Causes behind Battery Failures

In this study, the key forensic analysis techniques will be introduced and the rationales to link between failure mechanism and battery failure modes will be presented. The forensic analysis method is a powerful tool to identify the root causes behind battery failures.

The properties of the interface between electrode active materials and electrolyte are known to have profound effects on the performance of Li-ion batteries (LIBs). A large amount of research has so far been devoted to modifying the surfaces of active materials in order to enhance the overall performance of the electrodes. Majority of the research has resorted to inorganic oxide coatings, presumably due to their chemical stability, and different beneficial effects have been claimed for both cathode and anode materials. Relatively there have been fewer studies on polymeric coating. Compared with the inorganic ones, the polymeric coatings require much lower processing temperature, and when used water as solvent, can be considered as more environmentally-friendly alternative. In addition, the rich chemistry of the polymeric coating intrinsically possess a greater flexibility for dealing with wide varieties of active materials and electrolytes for maximum performance.

For LIB anodes, there are two important issues to deal with for achieving high-energy and high-power performance. First, decomposition of electrolyte at the anode surface takes place at sufficient low potential leading to the formation of a passivation film, known as solid electrolyte interphase (SEI). Formation of the SEI consumes Li ion inventory and hence reduces the overall capacity of the battery cell. Therefore, the amount of the stable SEI layer should theoretically kept at a minimum. Secondly, the power densities for the state-of-the-art graphite electrodes remain insufficient.

In this presentation, we report our studies on developing various polymeric coatings for LIB anodes, particularly for graphite and graphite/Si composite. It is demonstrated that the properties of the anodes in different aspects, such as chemical/electrochemical, mechanical, and wetting behaviors, can be substantially changed with various combinations of different polymer blends. It is shown that both the cycle life and the power performance of the anodes can be remarkably enhanced by simple polymer coating method.

# Manufacturing and Performance of solid-state thin-film batteries

<sup>2</sup>*Rheinisch-Westfälische Technische Hochschule (RWTH) Aachen, Institut für Gesteinshüttenkunde,  
Mauerstr. 5, 52064 Aachen, Germany*

*s.uhlenbruck@fz-juelich.de*

The combination of solid ceramic-like electrolytes with inorganic electrodes, thus creating an all solid-state battery, requires a sophisticated co-processing, taking into account the different chemical and thermal stabilities of the applied materials. *Thin-film* batteries allow – on the one hand – a detailed analysis of the compatibility of active storage material and the electrolyte because of dense layer morphology (ideal case) and well-defined planar interfaces. On the other hand, thin-film batteries also have the potential for energy storage solutions in applications with short-term or low power consumption. Optionally, a stacking of active thin layers can increase the energy content.

In general, the deposition and crystallization of a functional layer for solid-state battery cells requires a heat incidence that can lead to an undesired and detrimental diffusion of constituents into the substrate or into adjacent components, to mechanical stresses and resulting cracks due to different coefficients of thermal expansion, or even to a decomposition of parts of the battery. The purpose of this work is a comparison of different materials, Lithium-oxynitride (LiPON) based and Lithium-Lanthanum-Zirconium-oxide (LLZ) based electrolyte materials, and different thin-film deposition processes (for example physical vapor deposition, spin-coating, dip-coating, ink-jet-printing) that are applied to thin-film solid-state battery cells, and their impact on the microstructure, the inter diffusion and, as a result, on the performance of the cells. Analysis was done, among others, by high-resolution scanning electron microscopy, secondary ion mass spectrometry, nuclear reaction analysis, Rutherford backscattering, electrochemical impedance spectroscopy, galvanostatic charge-discharge measurements and cyclic voltammetry.

As an outlook, the economic feasibility of thin-film deposition technologies like physical vapor deposition is discussed.

# Aqueous Zinc-Ion Batteries based on Prussian Blue Derivatives

Fabio La Mantia<sup>1,2</sup>

<sup>1</sup>Energiespeicher- und Energiewandlersysteme, Universität Bremen, Badgasteiner Str. 1, 28359 Bremen, Germany

<sup>2</sup>Fraunhofer Institut IFAM, Wiener Straße 12, 28359 Bremen, Germany  
fabio.lamantia@rub.de

Stationary battery systems have been proposed as plausible alternative for the storage of renewable energy sources in power grid. For this application, aqueous electrolytes are preferred, which offer several important advantages compared to organic electrolytes, i.e. non-flammability, cost effectiveness, as well as higher ionic conductivity, salt solubility and thermal capacity. However, most of the aqueous batteries have low voltage, short life cycle, and low stability, deriving from the potential stability window of the electrolyte. We have investigated a zinc-ion battery based on copper hexacyanoferrate (CuHCF) and

Potential profile of CuHCF (solid line) and Zn film (dashed line) at different cycles.

metallic Zn in different aqueous electrolytes. CuHCF works as host structure for the insertion of many different monovalent cations, such as Na<sup>+</sup>, K<sup>+</sup>, and NH<sub>4</sub><sup>+</sup>, and it works as well as hosting structure for different divalent cations. Among them, Zn<sup>2+</sup> can be intercalated at two potentials, equal to 0.8 V (NHE) and 1.1 V (NHE). The average operational voltage of this battery system is equal to 1.73 V at a current rate of 60 mA g<sup>-1</sup> (1 C). In a ZnSO<sub>4</sub> aqueous solution at pH value of 6, the system appears stable for more than 100 cycles, and delivers a specific power of 480 mW g<sup>-1</sup> at a current rate equal to 10 C, considering both mass of positive and negative electrodes. The performances of the battery are affected strongly by the intercalation of Zn<sup>2+</sup> in the CuHCF structure, and by the hydrogen evolution on the surface of the zinc electrode. In particular, it has been observed that H<sub>2</sub> evolution can cause a shift of pH near the surface of the zinc electrode, favoring the stabilization of ZnO, which hinders the performances of the battery. In fact, ZnO is blocking the reaction of dissolution of zinc, due to its insulating character. This detrimental mechanism is blocked when the surface of the zinc becomes rougher, thus enhancing the zinc deposition reaction, which results in a flower-like structure. Moreover, the effect of the anion of the zinc salt on the cycle life and stability of the battery has been analyzed.

# Symposium 3: Investigation of the growth of a SEI-like surface layer on $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$ high voltage cathodes

Klaus Wedlich, Carsten Korte, Detlef Stolten  
Institute of Energy and Climate Research (IEK-3) Forschungszentrum Jülich GmbH  
D-52428 Jülich, Germany, e-mail: k.wedlich@fz-juelich.de

The utilization of high voltage cathode materials (HVC), which provide cell voltages of over 4.5 V, is a promising strategy to increase the specific energy and power density of Li-Ion-Batteries (LIB's). In contrast to commercial available 4 V-cathodes, the electric potential of HVC's exceed the stability window of conventional electrolytes, based on alkylcarbonate solvents [1]. This results in the formation of a surface layer on the cathode analogous to well-known anodic SEI [2-4]. Assuming a simple layer growth, we developed a geometrical model of anodic SEI growth. Such a model implies a linear dependence between the capacity-based state-of-health (SoH-Q) and the impedance-based (cell resistance) state-of-health (SoH-R). The change of the capacity ( $\Delta Q$ ) with time exhibits a square root time dependency which implies a diffusion controlled growth of the surface layer on the anodes.

Adapting this model to high-voltage  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$ -cathodes (LNMO) which were cycled 300 times and more, show a linear correlation between SoH-Q and SoH-R. A non-square root time dependency of  $\Delta Q$  exhibits a non-diffusion-controlled process. The incremental capacity (IC), which can be obtained from charge/ discharge curves, shows a steady capacity change for a broad potential range. When using carbon, LTO and metallic Li as anode materials we investigate strong differences in the degradation behaviour of these cells. As the capacity loss is caused by the consumption of active lithium in the cathodic and anodic surface layers, cells with Li-Anodes show only a moderate degradation in contrast to cells with carbon or LTO anodes, which are not able to compensate the loss of active material. Carbon anodes additionally seem to promote the degradation of the cells. By constructing LTO-limited cells we found that the degradation is mainly driven by the capacity loss of the cathode. We identified the growth of a surface layer as main ageing mechanism in HVC's.

A characterisation and comparison of the surface layers of the different electrodes is performed by SEM, XPS-analyses and ToF-SIMS measurements.

**Figure 1:** surface layer on a LNMO cathode before and after 83 cycles

# Electrode properties of the restacked MnO<sub>2</sub>-based nanosheets with vacancy defects

Shinya Suzuki, Masaru Miyayama

Department of Applied Chemistry, School of Engineering, The University of Tokyo  
7-3-1 Hongo, Bunkyo-ku, 113-8656 Tokyo, Japan  
sin@fmat.t.u-tokyo.ac.jp

## [Introduction]

The Li–Ni–Co–Mn oxide system is a promising alternative to LiCoO<sub>2</sub> or LiNi<sub>x</sub>Co<sub>1-x</sub>O<sub>2</sub> cathode materials, owing to the large capacity and low cost, and dependence of the electrode properties of Li–Ni–Co–Mn oxide on chemical composition have been extensively investigated. Ni–Co–Mn oxide nanosheets are the potential electrode materials for thin-film energy storage devices. But few studies have been conducted on the preparation of Ni–Co–Mn oxide nanosheets. We tried to prepare novel redoxable nanosheets of Ni–Mn oxide as the stage prior to the formation of Ni–Co–Mn oxide nanosheets. In the process, we obtained the novel nanosheets with vacancy defects. In this study, the restacked Ni–Mn oxide nanosheets with vacancy defects were prepared and its electrode properties for lithium-ion batteries were examined.

## [Experimental]

A layered Na<sub>0.55</sub>Ni<sub>0.25</sub>Mn<sub>0.75</sub>O<sub>2</sub> was prepared by solid state reaction. Nanosheets of Ni–Mn oxide with a chemical composition of H<sub>x</sub>Ni<sub>0.19</sub>Mn<sub>0.75</sub>O<sub>2</sub> (N19M75 nanosheets) were obtained by exfoliation of the proton-exchanged form of Na<sub>0.55</sub>Ni<sub>0.25</sub>Mn<sub>0.75</sub>O<sub>2</sub>. The reaction of N19M75 nanosheets with HNO<sub>3</sub> resulted in the formation of a restacked material with a chemical composition of H<sub>x</sub>Ni<sub>0.12</sub>Mn<sub>0.75</sub>O<sub>2</sub>. Then, H<sub>x</sub>Ni<sub>0.12</sub>Mn<sub>0.75</sub>O<sub>2</sub> (N12M75) nanosheets were obtained by exfoliation of H<sub>x</sub>Ni<sub>0.12</sub>Mn<sub>0.75</sub>O<sub>2</sub>. Restacked N12M75 nanosheets were prepared by the reaction with LiOH solution, and the electrode properties were examined for the prepared restacked materials.

## [Results and Discussion]

Lateral dimensions were 50–500 nm for N19M75 nanosheets, which were composed of 1–2 oxide layers. N12M75 was obtained by re-exfoliation of restacked H<sub>x</sub>Ni<sub>0.12</sub>Mn<sub>0.75</sub>O<sub>2</sub> nanosheets. **Figure 1** shows atomic force micrograph of N12M75 nanosheets (upper) and cross section of the region indicated by the line in the upper image (lower). The structure of N19M75 and N12M75 nanosheets was the same, and this indicates that dissolution of Ni occurs without any structural change, resulting in nanosheets with vacancy defects. Restacked N12M75 nanosheets were prepared by the reaction with LiOH solution, and the chemical composition of the restacked compound was determined by ICP-AES, yielding Li<sub>0.23</sub>Ni<sub>0.12</sub>Mn<sub>0.75</sub>O<sub>2</sub>·0.26H<sub>2</sub>O. **Figure 2** shows the discharge and charge curves of the restacked N12M75 nanosheets. At initial discharge and subsequent charge, restacked N12M75 nanosheets showed capacities of 160 and 180 mAh g<sup>-1</sup>, respectively. The restacked N12M75 nanosheets exhibited inferior cycling durability may be due to the low electronic conductivity. The vacancy defects generated by Ni dissolution may serve as ionic conducting paths for small cations such as H<sup>+</sup> and Li<sup>+</sup> penetrating through oxide layer. Lithium-ion diffusion behavior through nanosheets with vacancy defects is on investigation and will be reported.

**Figure 1.** Atomic force micrograph of N12M75 nanosheets (upper), and cross sectional analysis by the line (lower).

**Figure 2.** Discharge and charge curves of restacked N12M75 nanosheets. The current density was 100 mA g<sup>-1</sup>. The numbers in the figure indicate cycle number.

# Superior electrochemical performance of Li-rich $\text{Li}_{1.188}\text{Ni}_{0.198}\text{Co}_{0.087}\text{Mn}_{0.553}\text{O}_2$ cathode material by coating Li–La–Zr–O solid electrolyte

E-mail: huangl@xmu.edu.cn; sgsun@xmu.edu.cn

**ABSTRACT:** Li-rich Mn-based layered oxide materials have been received great attention owing to the characteristic of high discharge capacity above 250 mAh/g between 2.0–4.8 V, relative low cost and high thermal stability, but this oxide material also has other drawbacks such as poor rate capacity, large irreversible capacity loss during the first cycle and voltage fade. Surface coating on the active material is considered as an effective strategy to suppress the side reaction in the surface of electrode and can apparently improve cell's electrochemical performance. In this report, Li-rich Mn-based layered oxide  $\text{Li}_{1.188}\text{Ni}_{0.198}\text{Co}_{0.087}\text{Mn}_{0.553}\text{O}_2$  (LMO) material is successfully coated with Li–La–Zr–O solid electrolyte (LLZO) by sol–gel process. Both LLZO-coated LMO and pristine materials are characterized by x-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), inductively coupled plasma–atomic emission spectrometry (ICP–AES) and electrochemical impedance spectroscopy (EIS) to understand the effect of LLZO coating layer on the LMO materials. After 450 cycles at 1 C, the 2 wt% LLZO coated LMO material exhibits a significant cycle stability of 193 mAh/g capacity with a capacity retention of 84.8 % compared to the LMO material of 125.4 mAh/g with a capacity retention of 54.1 %, which could mainly own to the improvement of the surface stability and suppressing the side reactions by Li–La–Zr–O coating layer. In addition, 2 wt% LLZO coating layer could also improve the rate performance of the electrode by reducing interfacial charge–transfer resistance obviously.

Hierarchical Mn<sub>2</sub>O<sub>3</sub> hollow microspheres of diameter about 6–10  $\mu\text{m}$  were synthesized by solvent-thermal method. When served as anode materials of LIBs, the hierarchical Mn<sub>2</sub>O<sub>3</sub> hollow microspheres could deliver a reversible capacity of 580 mAh g<sup>-1</sup> at 500 mA g<sup>-1</sup> after 140 cycles, and a specific capacity of 422 mAh g<sup>-1</sup> at a current density as high as 1600 mA g<sup>-1</sup>, demonstrating a good rate capability. Ex situ X-ray absorption near edge structure (XANES) spectra reveals that, for the first time, the pristine Mn<sub>2</sub>O<sub>3</sub> was reduced to metallic Mn when it discharged to 0.01 V, and oxidized to MnO as it charged to 3 V in the first cycle. Furthermore, the XANES data demonstrated also that the average valence of Mn in the sample at charged state has decreases slowly with cycling number, which signifies an incomplete lithiation process and interprets the capacity loss of the Mn<sub>2</sub>O<sub>3</sub> during cycling.

Silicon (Si) has attracted much attention as anode material due to its huge theoretical capacity, while there are critical disadvantages of a low electronic conductivity and significant volume changes during Li-insertion/extraction. We have revealed that the performance of composite electrodes, consisting of transition metal silicides and Si, can be improved by the synergetic effects of their properties [1-4]. In particular, we found that lanthanum silicide (La-Si) is very effective [1-2]. In contrast, the effect of other rare-earth metal silicides on the performance has never explored yet. In this study, we chose samarium (Sm), gadolinium (Gd), and dysprosium (Dy) as rare-earth elements to be silicides, and investigated the anode performance of composite electrodes consisting of the silicides and Si.

Composite active materials of rare-earth metal silicides (*Ln*-Si) and elemental Si were synthesized by an arc melting method. Thick-film electrodes of the active material powder were prepared on current collectors of copper foils by a gas-deposition (GD) method [1-4]. An elastic deformation property of silicide electrodes was measured by an indentation test using a dynamic ultra-micro hardness tester. Electrode performances were evaluated in a beaker-type three-electrode cell using 1 M LiBF<sub>4</sub>/propylene carbonate as the electrolyte. Charge-discharge tests were carried out at 303 K with potential ranges of 0.005–2.000 V vs. Li/Li<sup>+</sup> under 3.0 A g<sup>-1</sup>. This current density corresponds to a current rate of 1.2 C.

Figure 1 shows the variation in the discharge capacities of these composite electrodes following the increase in the number of charge-discharge cycles. In contrast with the Si electrode showing a quick capacity decay caused by its pulverization, the all composite electrodes exhibited improved performances. In particular, the Gd-Si/Si electrode maintained a very large discharge capacity of 840 mA h g<sup>-1</sup> even after 1000 cycles, which clearly demonstrating its distinctly excellent performance [4]. The discharge capacity of Gd-Si/Si is much larger than the graphite's theoretical capacity of 372 mA h g<sup>-1</sup>. To evaluate the contribution of these silicides to the composite electrodes' capacities, we synthesized silicide electrodes composed of Sm-Si, Gd-Si, and Dy-Si. These silicide electrodes showed very small capacities of around several ten mA h g<sup>-1</sup> though the capacities stably maintained for a long cycle, as in the case of La-Si electrodes [1,2]. This indicates that the composite electrodes derive nearly all capacities not from silicides but from elemental Si. Electrical conductivities of *Ln*-Si powders were measured under a uniaxial press using a two probes method. The *Ln*-Si powders showed three orders of magnitude higher conductivity than a Si powder, and that there was no difference in the conductivity was observed among the *Ln*-Si powders. On the other hand, Gd-Si exhibited a more elastic property in comparison with other silicides (Table 1), indicating that it released effectively the stress from Si during Li-insertion/extraction and suppressed silicon's pulverization.

**Fig. 1** Cycling performances of *Ln*-Si/Si composite electrodes (*Ln*: La, Sm, Gd, and Dy).

**Table 1** Mechanical properties of various rare-earth metal silicides (*Ln*-Si): reference breaking strength for *Ln*-Si particles and indentation work rate ( $\eta_{it}$ ) for *Ln*-Si thick-film electrodes. Values in parentheses indicate the standard deviation of the measured values.

	Reference breaking strength / MPa	$\eta_{it}$ / %
Si	374 (±54.7)	13 (±2.0)
La-Si	237 (±37.5)	31 (±2.1)
Sm-Si	206 (±26.1)	28 (±2.1)
Gd-Si	155 (±37.2)	41 (±3.2)
Dy-Si	196 (±17.3)	26 (±2.2)

## Abstract

NASICON-structured NaTi<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> has been considered as an outstanding potential cathode material for Na-ion batteries (NIBs) because of its good Na-ion intercalation reversibility and extremely small structural changes during charge/discharge cycling.<sup>1</sup> Despite these advantages, NaTi<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> suffers from intrinsically poor electronic conductivity, which leads to poor charging/discharging rate performance of NIBs. Up to now, several effective ways have been proposed to improve the electrochemical properties such as specific capacity and cycling stability, including reduction of the particle size to nanoscale, the addition of a surface coating and the synthesis of composite materials with conductive carbons.<sup>2</sup>

In particular, the composites of NASICON-structured materials with carbonaceous materials such as mesoporous carbon and graphene or reduced graphene oxide (rGO) has been recently proposed to enhance electronic conductivity of the electrode for improving the cycling performance.<sup>3</sup> Graphene acts as a template due to its high specific surface area not only to deposit nano-sized metal oxide but also to connect the nano particles along a 2-dimensional conduction path. Furthermore, graphene can provide a void space against the volume changes of the metal oxide particles during lithium ion insertion/extraction process, which can improve the cycling performance. However, previously reported methods to fabricate of these composites require multistep, time-consuming processes, and complicated.<sup>4</sup> Moreover, in this multistep method, the sodiation and heat treatment steps unfavorably affect the size, morphology and homogeneity of the resulting NaTi<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub> particles. Accordingly, their electrochemical properties showed only a marginal improvement compared with the bare NaTi<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub>.

In this study, we report a simple one-pot synthesis of NaTi<sub>2</sub>(PO<sub>4</sub>)<sub>3</sub>/rGO nanocomposites *via* a microwave-assisted solvothermal method that combines the advantages of simplicity and efficiency. Electrodes prepared from the nanocomposites provide excellent cycling performance and rate capability, indicating great potential for their use in NIBs. More details on the synthetic procedure, electrochemical and structural properties will be presented at the meeting.

## Abstract

A  $\text{Li}_2\text{O}-2\text{B}_2\text{O}_3$  coated  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode active material was synthesised to enhance the thermal stability of  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  electrodes used in lithium ion batteries. The  $\text{Li}_2\text{O}-2\text{B}_2\text{O}_3$  coating prevented the surface of the  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  electrode from being directly exposed to the liquid electrolyte, thereby suppressing the dissolution of Mn from the electrode surface into the electrolyte and the undesirable formation of a solid-electrolyte-interphase layer. The surface-coated electrode showed 81% capacity retention during high-temperature (60 °C) cycling. The results of the electrochemical impedance spectroscopy (EIS) indicated that the improved performance of the surface-coated electrode slowed the increase in cell impedance during cycling. The  $\text{Li}_2\text{O}-2\text{B}_2\text{O}_3$  coating effectively slowed the surface of the  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  electrode from being directly exposed to the liquid electrolyte, thereby suppressing the dissolution of  $\text{Mn}^{3+}$  ions from the surface of the spinel cathode active material into the electrolyte. The  $\text{Li}_2\text{O}-2\text{B}_2\text{O}_3$  coating will pave the way for improving the electrochemical cycling of various cathode active materials at elevated temperatures

Electrochemical surface plasma resonance (EC-SPR) is a powerful instrument for in-situ observation of SEI formation. Propagation constant of surface plasma is sensitive to variation in the refractive index (RI) at the surface of metal film of electrode [1]. SPR provides high sensitivity, real time monitoring, and label free detection [2]. Gold electrode is used to detect the real time SEI formation in accompanied with electrochemical reaction. The optical response of the SEI strongly affects the SPR angles due to the RI is changing.

In this study, EC-SPR is used to simulate the SEI formation in electrochemical reaction of lithium ion battery. 1M LiPF<sub>6</sub> in EC/EMC (sample A) and 1M LiPF<sub>6</sub> + 0.1 wt% Lithium benzimidazole (LIB) in EC/EMC (sample B) were used in this research. The experiment sets up in a scan rate of 0.5 mV/s in order to characterize the salt effect on SEI formation. Figure 1a and b show that sample B has a higher delta angle (Fig. 1a) and lower intensity (Fig. 1b) compare with sample A only show lower delta angle and higher delta intensity. Variation on delta degree is correlated to the different SEI formation [3].

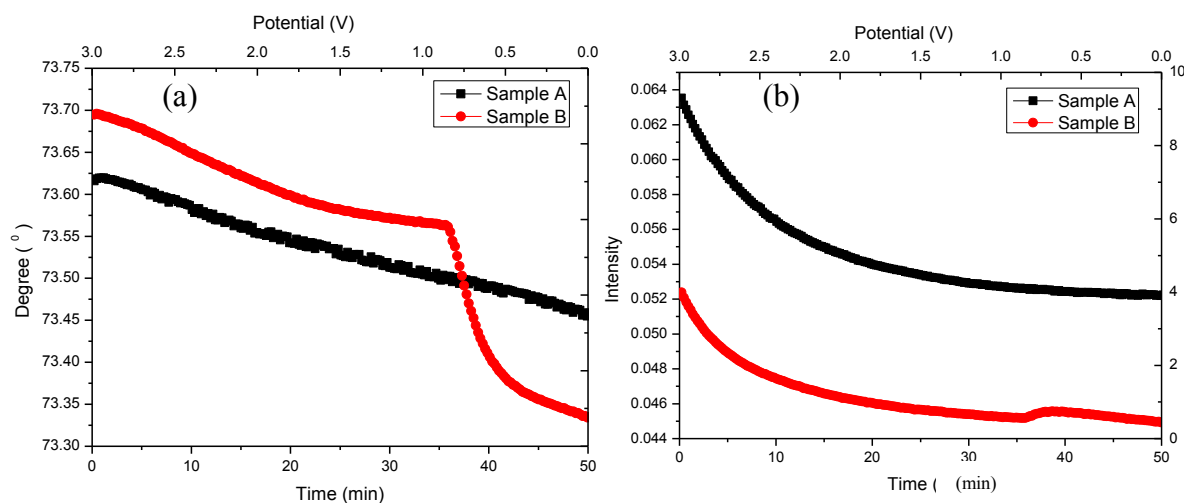

Fig. 1 a) Sensogram and b) Intensity detection of Sample A and Sample B

Sample	Delta Angle	Delta Intensity
Sample A	0.057	0.012
Sample B	0.429	0.008

Lithium-ion batteries (LIBs) are common in portable electronics and they have also attracted significant interest in electric vehicles and large-scale storage applications. Electrochemical processes in LIBs produce microstructural evolution of the porous electrode material, altering the capacity, charging behaviour, durability and lifetime of the cells. Nowadays, intense research is devoted to develop new generations of advanced batteries with high energy density. For example, alloying Silicon anodes are promising electrodes with theoretical energy density up to  $\sim 4200$  mAh/g against the  $\sim 375$  mAh/g of graphite, which is still the most used anode material in commercial batteries. Silicon electrodes, however, have the drawback of exhibiting extreme volume changes during the lithiation process ( $\sim 300\%$  compared to  $\sim 10\%$  of graphite). Volume changes within a battery's constrained case involve mechanical strains on the fundamental components of the material, which eventually causes the battery to fail.

Non-destructive 3D X-ray imaging techniques are suitable for the study of these coupled electrochemical and mechanical phenomena, as they allow the visualization of the evolution of the microstructure properties of the LIBs during cycles of charge/discharge. Herein, we combine synchrotron radiation and lab-scale X-ray computed microtomography for the study of silicon-based LIBs.

**Figure:** Evolution of a half-cell battery (Li foil as anode at the left side, Si powder as cathode at the right side) during the first lithiation step at different degree of lithiation: a) fresh b)  $\sim 25\%$ , c)  $\sim 50\%$ , d)  $\sim 75\%$ . Volume changes of the electrodes cause the displacement of the separator, which eventually collapses causing the battery fail. X-ray tomography allows quantitative identification of the different lithiated-silicon phases.

For these experiments, bespoke designed, X-ray transparent, functional Si – Li cells were assembled to make possible *in situ* and *in operando* tests (i.e., simultaneous tomographic imaging and electrochemical testing). The observed microstructural volume changes are quantified using well-known geometric parameters. Full 3D strain/deformation measurements are performed using a digital volume correlation (DVC) technique. Results presented here throw light upon the large capacity loss during the first lithiation in alloying LIBs, facilitating the development of electrochemo-mechanical models based on the micromechanical observations.

Lithium-ion batteries are the most commonly used devices for energy storage in the market. However, their prospects are seriously restricted due to limited energy density, which prevents them from applications in the market of electric vehicles for long-range travelling. With a theoretical energy density of 2600 Wh kg<sup>-1</sup>, lithium sulfur batteries have been proved to be a perfect alternative since 2009 when researchers reported a novel lithium sulfur battery with improved specific capacity and cycling performance [1]. Furthermore, the non-toxic nature of sulfur renders it environmentally friendly, making Li-S batteries attractive for storage of renewable energy. In this study, one-dimensional carbonized polydopamine (C-PDA) shell were subtly designed employing the polymerization and graphitization of coated polydopamine layer with controlled thickness on pre-synthesized iron oxide nanotubes, followed by the infiltration of sulfur. The properties and performance of the composite (S@C-PDA) as the cathode material in lithium sulfur (Li-S) batteries were examined and evaluated. It was demonstrated that the prepared one-dimensional C-PDA shells have a diameter ~80 nm and a length of 200-300 nm; the sulfur particles could diffuse through the pores (diameter: ~3 nm) and be well dispersed at the polydopamine inner layer with a thickness of 8-15 nm (**Fig. 1(a)**). The assembled battery exhibited a high capacity at 1C (~800 mAh/g) with stable cycling of 200 cycles (**Fig. 1(b)**). In addition, it was demonstrated that the battery could run to 800 cycles with fair capacity at a current density of 2C/4C (**Fig. 1(c)**). The good performance is attributed to the good conductivity of C-PDA layer and the strong interaction between Li<sub>x</sub>S and C-PDA, the carbonized product of polydopamine which helps modify the carbon surface and is capable of trapping the soluble polysulfide in the electrolyte. The one-dimensional structure of C-PDA shell and the smaller pore size on the wall can also prevent the agglomeration of sulfur particles, contributing to the improved specific capacity and cycling stability. While the Li-S battery developed following this route still suffers from slight capacity decay during cycling, its high performance in capacity and cycling ability suggest a promising cathode material for future lithium sulfur batteries.

**Fig. 1.** TEM images (a) of single-walled C-PDA nanotubes impregnated with sulfur with a scale bar of 200 nm; Cycling performance of C-PDA@S nanotubes at a current density of 1C for 300 cycles (b) and 2C/4C for 800 cycles.

# Highly Concentrated Electrolytes for 5-V Cathodes

Minoru Inaba, Rin Masuhara, Yusuke Shimizu, Michihiro Hasinokuchi, and Takayuki Doi  
Department of Molecular Chemistry and Biochemistry, Doshisha University  
1-3 Tatara-Miyakodani, Kyotanabe, Kyoto 610-0321, Japan  
minaba@mail.doshisha.ac.jp

Highly concentrated electrolytes have many unique properties,<sup>1-4</sup> such as  $\text{Li}^+$ -intercalation into graphite anode without EC,<sup>1,3</sup> suppression of  $\text{S}_8^{2-}$  ion dissolution in Li-S batteries, etc., and is attracting much attention of many researchers. In highly concentrated electrolytes, all solvent molecules are strongly coordinated with  $\text{Li}^+$  ions, and hence the stability of the electrolytes against oxidation is improved significantly. Yoshida et al. reported that  $\text{LiCoO}_2$ , which is a 4-V cathode, can be charged and discharged in a LiTFSI/triglyme (1:1) electrolyte with good cycleability,<sup>3</sup> though triglyme is an ether compound and usually cannot be used as solvent.

5-V cathodes, e.g.  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  and  $\text{LiCoPO}_4$ , are promising for the next-generation LIBs with high energy densities. Unfortunately no electrolyte systems that tolerate the highly oxidative 5 V cathode have been reported so far. In the present study, we investigated the effect of concentration on the stability of highly concentrated electrolytes,  $\text{LiPF}_6/\text{PC}$  and  $\text{LiBF}_4/\text{PC}$ , against a 5-V cathode,  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  to realize 5 V LIBs with high energy densities.

Figure 1 compares charge/discharge curves of a 5-V spinel  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  in standard ( $0.83 \text{ mol kg}^{-1}$ , 1 M,  $\text{Li}/\text{PC} = 11.8$ ) and highly concentrated ( $4.9 \text{ mol kg}^{-1}$ ,  $\text{Li}/\text{PC} = 2$ )  $\text{LiBF}_4/\text{PC}$  at  $30^\circ\text{C}$ . The charge/discharge rate of C/10 was employed to exaggerate electrolyte decomposition. Though the  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  can be charged and discharged in both electrolytes, the irreversible capacity ( $Q_{\text{irr}}$ ) in 1 M  $\text{LiBF}_4/\text{PC}$  was high ( $76 \text{ mAh g}^{-1}$ ) because of vigorous electrolyte decomposition. In contrast,  $Q_{\text{irr}}$  was significantly reduced in the concentrated electrolyte, which indicated that stability against oxidation was improved in the highly concentrated electrolyte. Similar tendency was also observed in highly concentrated  $\text{LiPF}_6/\text{PC}$  electrolytes, though polarization on charging and discharging were much higher.

The half-cell was fully charged to 5.0 V, and kept at  $60^\circ\text{C}$  for 3 days in  $\text{LiPF}_6/\text{PC}$  electrolytes. The amount of Mn deposited on lithium counter electrode was evaluated by ICP as a measure of dissolved Mn ions. Figure 2 shows the variation of the amount of Mn deposited on lithium counter electrode with  $\text{Li}/\text{PC}$  ratio. The amount of dissolved Mn ions decreased with increasing  $\text{Li}/\text{PC}$  ratio, which indicated that the use of highly concentrated electrolytes is also effective for suppressing Mn ion dissolution.

This work was supported by a Kyoto Area Super Cluster Program, Japan Science and Technology Agent (JST), Japan.

## Abstract

Energy has been a key issue in this generation, with various energy resources, such as solar and wind power, being investigated. These renewable energy resources are attractive, but the method of storing the energy is one of the main problems. Redox Flow batteries designed to store energy in the electrolyte can address the energy storage problem[1]. Polyoxometalates (POMs), with versatile, tunable properties, undergo multielectrons redox reactions which may meet the requirements of high performance Redox Flow Batteries.

Research conducted to date has focused on the electrochemical characteristics of different combinations of Keggin polyoxometalates ( $\text{XM}_m\text{O}_{40}^{n-}$ ). The initial goal of the project is to select suitable polyoxometalate species that can be used for Redox Flow Batteries.

Various counter – cation exchanged POMs have been examined.  $\text{Li}_3$ ,  $\text{Na}_3$ ,  $\text{Mg}_{1.5}$  and  $\text{Ca}_{1.5}$  salts POMs have been synthesized and tested. Generally, spectra for 1A or 2A salts showed 3 redox couples, but the peak positions are slightly different. The effects of 1A or 2A cations on cell potentials are fairly minor.

Cation of phosphorous, arsenic and silicon were compared here by testing  $\text{XMo}_{12}\text{O}_{40}^{3-/4-}$  and  $\text{XW}_{12}\text{O}_{40}^{3-/4-}$  forms ( $\text{Li}_3\text{PMo}_{12}\text{O}_{40}$ ,  $\text{Li}_3\text{AsPMo}_{12}\text{O}_{40}$ ,  $\text{Li}_4\text{SiMo}_{12}\text{O}_{40}$ ,  $\text{Li}_3\text{PW}_{12}\text{O}_{40}$ ,  $\text{Li}_4\text{SiW}_{12}\text{O}_{40}$ .) The predicted behavior of P, As, and Si substituted Keggin ions is based on the negative charge density of the compound affecting its redox potential. The number of redox couples is not affected by the heteroatom charge..

$\text{Li}_4\text{PMo}_{11}\text{VO}_{40}$ ,  $\text{Li}_5\text{PMo}_{10}\text{V}_2\text{O}_{40}$ , and  $\text{Li}_6\text{PMo}_9\text{V}_3\text{O}_{40}$  mixed addenda POMs were also compared. Each compound exhibits multiple redox couples. Different reduction and oxidation peaks appear compared to pure  $\text{Li}_3\text{PMo}_{12}\text{O}_{40}$ . The mechanism of addenda element effects on POM redox properties is still unclear, but the mixed addenda elements play an important role in determining the redox properties. Investigation of the mix addenda POMs is the focus of current investigations.

Charge/discharge tests of  $\text{Li}_3\text{PMo}_{12}\text{O}_{40}$  show relatively high coulombic efficiency ( $\sim 90\%$ ), which suggests that the reaction is stable during the experiment. In other words, the POM can be reversibly reduced and oxidized with minimal degradation. which validates the possibility of using POMs in non-aqueous media for RFBs.

Lithium-ion batteries occupy a large and increasing share of the energy storage device market as a result of their excellent performance in terms of long-life, energy density and high safety. Among the various electrode materials for LIBs, graphites which are representative of carbon materials have been the most commonly used negative electrode materials due to their low working potential close to lithium metal anode, and remarkable cycling performance. As lithium-ion cells typically operate beyond the thermodynamic stability of organic electrolytes, the reduction products arising from chemical reactions during the first few cycles form passivating films on the carbon anode surface, as we call it solid electrolyte interphase (SEI).[1] Such SEI, which is comprised of electrochemically insulating layer, plays important roles of preventing the further electrochemical reactions between electrode surface and electrolyte and enabling only lithium ions tunnel through the layer. It is well known that the formation of SEI layers is a determinant factor on the performance of LIBs, affecting cycle-life, life time, power capability and even safety.[2] While the SEI plays an essential part in delivering the best performance in cells, the development of SEI layers are caused by the irreversible reaction accompanying an electrolyte decomposition, which makes the coulombic efficiency to decrease during the first few cycles. When the stable SEI is not formed, any accidental misuse such as overcharge, high temperature exposure, and mechanic impact might damage the already formed SEI, resulting in more irreversible reaction during charging. The new anode surface, exposed to the electrolyte, immediately reacts with it to form a fresh thin protective film, which eventually leads to a poor cycleability and other undesirable properties in LIBs. Thus, to improve the performance of the cell, not only minimization of the electrolyte degradation but also thinner SEI film which provides an excellent passivating roll is required because thick and resistive SEI film is not favorable to battery operation.

Many research studies are thus focused on the improvement of the chemical nature and morphology of SEI. For the modification to SEI films having superior properties, several previous papers reported the polymer binder including the SEI ingredients and their electrochemical effects of LIBs.[3,4] The effects of the surface modification of the graphite electrode by the functional polymer binder, such as poly(acrylic acid), have been reported in several papers. Concretely, it has been demonstrated that the polyion complex layer, which have oxygen species as functional groups, could play the role like artificial SEI to assist the facile penetration of Li ions. Obviously, the stable and efficient operation of LIBs is closely connected with ingredients of surface films, morphology, and coverage feature.

Here we report that artificial pre-SEI, which is driven by Li ions containing polymeric binder with functional group (-COO-Li), can reduce the electrolyte decomposition and enhance the initial coulombic efficiency and cycleability. Furthermore, electrochemical performance is compared for SEI films that are produced from some different binders, in which different degree of lithium quantity is included in the polymer matrix. Li containing polymeric binder is a favorable candidate for the development of carbonaceous materials having high surface area and small particle size.

# Characterizing Interfacial and Bulk Phase Processes in LIB Using EIS

Jianbo Zhang<sup>1,2\*</sup>, Jun Huang<sup>1</sup>

<sup>1</sup> State Key Laboratory of Automotive Safety and Energy, Tsinghua University, Beijing, China, 100084

<sup>2</sup> Beijing Co-innovation Center for Electric Vehicles, Beijing Institute of Technology, Beijing 100081, China

[jbzhang@mail.tsinghua.edu.cn](mailto:jbzhang@mail.tsinghua.edu.cn)

Electrochemical Impedance Spectroscopy (EIS) is a powerful electrochemical analysis technique known for its unique capability to differentiate between electrochemical processes of various natures. On the basis of widely different time-scales, EIS allows to reveal the limiting factors in reaction mechanisms, and mass-transport processes, thereby giving insight for the optimization of electrochemical devices.

The power of EIS to resolve electrochemical processes is often obscured by the complexity such as the frequency dispersion, time constants distribution, and spatial variation in real system under study. This talk gives a review of three major approaches to increase the resolution of EIS.

In the testing approaches, micro-sized single particles [1] and ultra-thin film [2] were employed as the test objects to greatly suppress the spatial distribution. Sharp and clear impedance spectroscopy amenable to regression analysis were obtained. Reference electrode [3] was introduced into the LIB to differentiate the impedance of the positive and negative electrodes. In the analysis approach, measurement model [4] was proposed to explore the error structures in the measured impedance and to generate weighting coefficients [5] to be used in the regression. Distribution of the relaxation times [6] was taken into consideration in regression with a general multiple RC circuits connected in series. In the modeling approach, building more structural information of the electrode into the model greatly enhanced the power of prediction. Transmission line model [7] improves over the lumped equivalent electric circuit for planar electrode by assuming a distributed constant along the pores of the electrode. Newman's model [8] further takes into account the diffusion inside the active particles in the porous electrode.

In our recent work [9][10], a three scale EIS model was developed to take into account the agglomerates that frequently exist in the electrodes of LIB. The model first mathematically describes the electrochemical reactions and species transport inside the micron-sized agglomerate consisting of submicron-sized primary particles, and then extends the agglomerate model to the whole porous electrode using the Newman's approach. Compared with the existing two-scale impedance models, the present model is featured with a refined description of the structure of the electrode/electrolyte interface at the primary active material particle, and an analytical formulation of electrochemical reactions and species transport inside the agglomerates. The model is validated using electrochemical impedance spectroscopy (EIS) data of an NMC positive electrode in a three-electrode lithium-ion cell over a wide range of SOC. The identified values of key model parameters are corroborated by results from other experiments or the literature. A parametric study reveals that the characteristic frequency of lithium ion diffusion in the electrolyte can be comparable or even smaller than that in the active material particle. As a result, EIS models capable of distinguishing between the solid phase diffusion and liquid phase diffusion should be used to extract the lithium ion diffusivities from impedance data.

hai-jung.peng@psi.ch

The stability of the electrolyte towards both the positive and the negative electrode is one of the key factors determining the long-term cycling performance of a lithium-ion battery. It is especially important when higher cycle rates are needed or when the electrode materials are operated at high potentials ( $>4.5$  V vs.  $\text{Li}^+/\text{Li}$ ) [1]. The latter includes lithium-rich nickel cobalt manganese oxide (called hereafter HE-NCM), which offers high energy density due to a higher operating potential but outside the electrolyte stability window. Alkoxide anion, which is a reduction product of linear carbonates, has been reported to play an important role in the multi-step electrolyte decomposition [2]. However, the consequences of this electrolyte degradation for the electrochemical performance of the cells are not yet well understood. In order to shed light on this issue, it is necessary to understand the parameters influencing the formation of the alkoxide anion.

In this work, the effects of current density and upper cut-off potential on the formation of the alkoxide anion were studied. Half cells based on conventional NCMs (NCM111 and NCM523) were compared to half cells including HE-NCM (with LP57 electrolyte, 1M  $\text{LiPF}_6$  in  $\text{EC}:\text{EMC} = 3:7$  wt %, in both cases). The occurrence of trans-esterification reaction, which provides an indication of the formation of the alkoxide anion, was detected by means of gas chromatography. Comparison of the results for cells cycled at  $C/2$  and  $C/10$  rates revealed the great impact of anode passivation on the extent of the trans-esterification reaction (and hence the production of alkoxide anion). In addition, the upper cut-off potential was also identified to be an important parameter, where higher potentials seem to mitigate the formation of the alkoxide anion. Further investigation of NCM111 full cells (based on electrochemical cycling, gas chromatography, and electron microscopy) suggested that electrolyte instability towards the anode (if not only the alkoxide anion formation) can eventually result in surface layer build-up on the cathode side. Therefore, stable anode passivation is not only essential for the anode performance but also for the state-of-health of the cathode and in turn the overall cell performance.

Nowadays, Li-ion batteries (LIBs) are the primary choice of power source for portable electronic devices, including mobile phones, laptops, as well as electric vehicles. The working principle of a LIB is to store energy in chemical form by using charge-balancing Li ions that reversibly insert into the electrodes. The structure and chemistry of the electrodes determines their functional mechanism, and the removal and insertion of Li ions can significantly affect structure. Consequently, the structure and phase evolution of LIB electrodes during battery charge and discharge can be complex, with these processes underpinning function and electrochemical performance of the whole battery. Therefore, a mechanistic understanding of the reaction pathways, i.e. the atomistic and molecular-scale origin of battery performance<sup>1-5</sup>, will enable the rational improvement of electrode materials and pave the way for entirely new battery systems. The suitable elemental contrast, relatively-large penetration depth, and non-destructive interaction with matter that neutrons offer couples with the fast-detection ability of modern instrumentation to enable neutron powder diffraction to probe, in real time, the bulk crystallographic changes of electrodes in functioning batteries, with such experimental approaches known as *operando* studies. In this presentation, examples of *operando* neutron powder diffraction studies of electrode materials performed using WOMBAT<sup>6</sup>, the high-intensity neutron powder diffractometer at the Australian Nuclear Science and Technology Organisation, will be presented, demonstrating the importance of diffraction techniques in battery research.

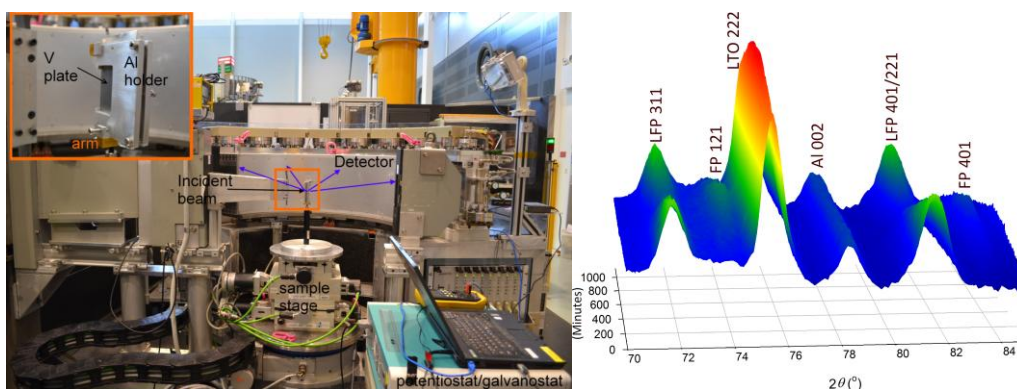

Figure 1. (Left) Experimental setup used for *operando* battery research with WOMBAT and (right) a contour plot of *operando* data from the  $\text{LiFePO}_4||\text{Li}_4\text{Ti}_5\text{O}_{12}$  pouch-type battery during charge-discharge.

# Synthesis and Catalytic Activity of Ni Doped $\text{CoFe}_2\text{O}_4$ Hollow Nanospheres as Bi-functional Catalysts for Lithium Air Batteries

Jing-Hua Tian\*, Yujiao Xu, Yue Fu, Jin Wang, Ruizhi Yang\*

College of Physics, Optoelectronics and Energy & Collaborative Innovation Center of Suzhou Nano Science and Technology, Soochow University, Suzhou, 215006, China

E-mail: jhtian@suda.edu.cn, yangrz@suda.edu.cn

Many metal oxides have been reported as a promising substitute for the precious metal based catalysts in fuel cells and metal-air batteries, due to their relatively abundance, affordable, environmentally-friendly.<sup>[1]</sup> Nevertheless, the intrinsic electrical conductivity of most metal oxide is quite poor due to their chemical structure and non-stoichiometric composition.<sup>[2]</sup>

In this study, we present the synthesis and investigation of Ni doped  $\text{CoFe}_2\text{O}_4$  hollow nanospheres ( $\text{Ni}_x\text{Co}_{1-x}\text{Fe}_2\text{O}_4$ ,  $0 \leq x \leq 1$ ) with a simple hydrothermal approach, hoping to improve the conductivity and catalytic active sites for the metal oxide, and then enhancing its electrocatalytic activity. The preliminary results are shown in Fig. 1. Fig. 1a) shows the SEM image of the original  $\text{CoFe}_2\text{O}_4$  nanospheres, the inset shows clearly the hollow structure. The morphology and structure of the nanospheres have no change with doping. Fig. 1b) shows the oxygen reduction reaction (ORR) curves of the  $\text{Ni}_x\text{Co}_{1-x}\text{Fe}_2\text{O}_4$  ( $x = 0, 0.25, 0.5, 0.75$ ), the onset potential shifts positively with the doping. A significant change occurs when  $x$  reaches 0.5 ( $\text{Ni}_{0.5}\text{Co}_{0.5}\text{Fe}_2\text{O}_4$ ), it shows the best catalytic activity with the highest diffusion limiting current density and about 60 mV positive shift for the half-wave potential comparing with  $\text{CoFe}_2\text{O}_4$ . Fig. 1c) shows the oxygen evolution reaction (OER) comparison of the  $\text{Ni}_x\text{Co}_{1-x}\text{Fe}_2\text{O}_4$ . The  $\text{Ni}_{0.75}\text{Co}_{0.25}\text{Fe}_2\text{O}_4$  ( $x=0.75$ ) exhibits the best catalytic activity with more negative onset potential (0.3 V vs. Ag/AgCl) and maximum current density ( $36.0 \text{ mA/cm}^2$  at 1.0 V). Fig. 1d) gives the electrochemical impedance spectra (EIS) of the  $\text{Ni}_x\text{Co}_{1-x}\text{Fe}_2\text{O}_4$  in  $\text{N}_2$ -saturated 0.1 M KOH at 0.8 V at a rotating speed of 1600 rpm. It shows clearly that the charge transfer resistance decreases with the increasing of Ni doping content, which is perfect correlation with the OER activity. Besides, we believe that with the Ni doping, the new redox couple  $\text{Ni}^{2+}/\text{Ni}^{3+}$  has a synergistic effect with the Co and Fe redox couples for the OER process, which likely explain why the best catalytic activity of the doped  $\text{CoFe}_2\text{O}_4$  could be achieved under suitable doping content.

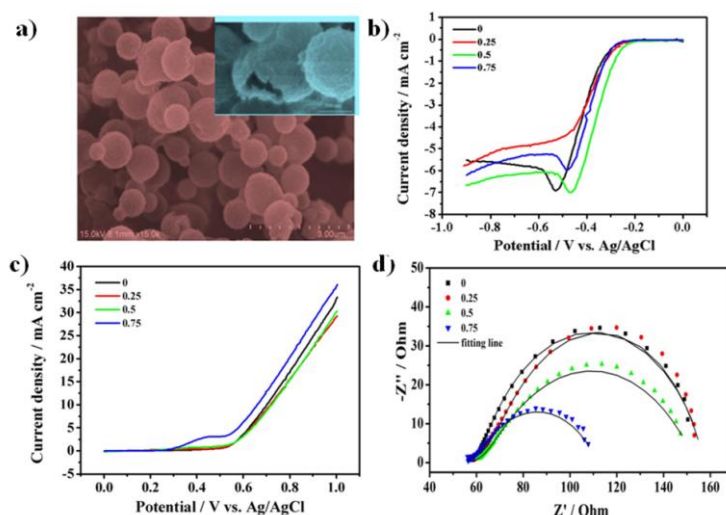

Fig. 1a) SEM image of the  $\text{CoFe}_2\text{O}_4$  hollow nanospheres, the inset is a typical broken nanosphere. b) ORR, c) OER and d) Nyquist plots of  $\text{Ni}_x\text{Co}_{1-x}\text{Fe}_2\text{O}_4$  ( $x = 0, 0.25, 0.5, 0.75$ ).

# Advances on the Zinc-Cerium Redox Flow Battery for Energy Storage

L.F. Arenas, C. Ponce de León, F.C. Walsh.

*Electrochemical Engineering Laboratory, Energy Technology Research Group, Faculty of Engineering and the Environment, University of Southampton SO17 1BJ, UK*

+44 2380598384, [lfam1g13@soton.ac.uk](mailto:lfam1g13@soton.ac.uk)

The zinc-cerium redox flow battery (Zn-Ce RFB) is an emerging utility-scale energy storage technology addressing the requirements for assimilation of renewable sources into the power grid [1]. High cell potential is its main advantage. The equilibrium cell potential of 2.48 V is the highest among practical, aqueous RFBs. Additional advantages include its lack of halide emissions and the moderate cost of the electrolyte, in comparison to vanadium reagents.

**Fig 1.** Open circuit cell potential vs. SOC of the Zn-Ce RFB.

In our recent work, the impact of cell potential components has been assessed, taking into consideration ohmic losses produced by electrolyte resistance, electrical connections and the resistivity of electrode materials. Activation overpotentials were also considered. This enabled cell potential vs. applied constant current density profiles for different operating conditions, identifying critical cell and cell stack design aspects and precise calculation of the resulting operating voltage. The resistivity of the main electrolyte compositions reported in the literature was measured at different operating temperatures and with varying acid content. The cell potential was also related to the state of charge (SOC) of the cell (Fig. 1), as established by the limiting cerium positive half-cell. Further research will focus on mass transport characterization using different positive electrode materials and cell monitoring.

The Zn-Ce RFB is based on the reduction of Ce(IV) to Ce(III) ions at the inert, positive electrode via the oxidation of metallic zinc at the negative electrodes, with the inverse reactions occurring during charge. Methanesulfonic acid is used as support electrolyte, enabling high concentrations of cerium and facilitating compact zinc deposits. Other works have focused on electrode materials, electrolyte composition and additives for performance enhancement [1]. This system is also been used as a develop platform for 3-D printing manufacture of flow cells.

**Keywords:** cell potential, cerium, energy storage, methanesulfonic acid, redox flow battery, zinc

# Enhancing electrochemical performance of layered oxide cathode materials for Li/Na ion batteries

Sihui Wang<sup>1</sup>, Xuehang Wu<sup>1</sup>, Shouding Li<sup>1</sup>, Jianghuai Guo<sup>1</sup>, Yixiao Li<sup>1</sup>, Yong Yang<sup>1,2</sup>

<sup>1</sup>State Key Lab of Physical Chemistry of Solid Surface & Department of Chemistry, <sup>2</sup>School of Energy Research, Xiamen University, Xiamen, 361005, China. e-mail: yyang@xmu.edu.cn

Li-ion battery systems have started to extend its roles from portable electronics, power tools to automobile applications such as hybrid and plug-in electric vehicles. However, it is necessary to enhance their electrochemical performance such as energy density and cycle life, for promoting their competition capability as vehicle power system. Obviously, electrode materials, especially positive electrode materials either working voltage or reversible capacity determine the energy density of the Li-ion batteries at mostly<sup>[1,2]</sup>.

In the presentation, some new research progress of the layered oxide cathode materials for Li/Na ion batteries will be reported. For example, we show that Ti modification could provide a promising way to realize this target with bifunctional role<sup>[3]</sup>. For example it is able to substitute Mn in the lattice framework and form a stable surface layer. It therefore results in a more stable energy density for the Ti-modified  $\text{Li}_{1.2}\text{Mn}_{0.54-x}\text{Ti}_x\text{Ni}_{0.13}\text{Co}_{0.13}\text{O}_2$  ( $x = 0.04, 0.08, \text{ and } 0.15$ ) materials during cycling. The evolution of dQ/dV curves show that the layered/spinel phase transformation is suppressed by the introduction of strong Ti-O bond in the framework. In addition, SEM, TEM, and EIS results confirm that more uniform and stable interface layer are formed on Ti-modified  $\text{Li}_{1.2}\text{Mn}_{0.54-x}\text{Ti}_x\text{Ni}_{0.13}\text{Co}_{0.13}\text{O}_2$  ( $x = 0.04, 0.08, \text{ and } 0.15$ ) materials compared with Ti-free  $\text{Li}_{1.2}\text{Mn}_{0.54}\text{Ni}_{0.13}\text{Co}_{0.13}\text{O}_2$ . The stable interface layer on the lithium-rich oxides is also beneficial to further reducing side reactions and resulting in stable surface layer resistance.

In addition, it is found that the introduction of  $\text{Zn}^{2+}$  in the Na-Ni-Mn-O system can effectively overcome the drawback of voltage decay when charged to a higher cutoff voltage ( $>4.0$  V), and significantly improve capacity retention compared to the unsubstituted material during cycling<sup>[4]</sup>. In addition, a smoother charge/discharge profile can be observed between 3.0 and 4.0 V for Zn-substituted samples, demonstrating that  $\text{Na}^+$ /vacancy ordering can be suppressed during sodium insertion/extraction.  $\text{Na}_{0.66}\text{Ni}_{0.26}\text{Zn}_{0.07}\text{Mn}_{0.67}\text{O}_2$  can deliver an initial capacity of  $132 \text{ mAh g}^{-1}$  at  $12 \text{ mA g}^{-1}$  with a high average voltage of 3.6 V and a capacity retention of 89% after 30 cycles.

Selina.Tillmann@uni-muenster.de

Electrodes for lithium-ion batteries, having a large inner surface area combined with good lithium-ion transport properties and a high electronic conductivity, are considered promising candidates for overcoming the current limitations of electrochemical energy storage by improving the energy and power density. To realize electrodes with improved transport properties for lithium ions, block copolymers serve as a template for the generation of highly ordered three-dimensional, low density metal foams, acting as an interpenetrating conductive electrode matrix.[1]

In this study the versatile morphologies of the block copolymer system poly(styrene)-*b*-poly(4-vinylpyridine) (PS-*b*-P4VP) were utilized by the incorporation and variation of the amount of the amphiphile (3-pentadecylphenol). Various morphologies such as double gyroid and hexagonal packed cylinders were identified (Figure 1) by Scanning Electron Microscopy (SEM) and Small Angle X-ray Scattering (SAXS) experiments.

Through selective removal of the amphiphile void spaces within the polymer template are created which are then filled with nickel via electroless plating. Subsequently, the polymer template is removed by temperature controlled degradation and the metal framework is recovered.[2]

Electrodeposition was used for the incorporation of active material into the porous current collector and the chemical composition of the deposit was analyzed applying X-ray Photoelectron Spectroscopy (XPS) and Raman Spectroscopy. To investigate the electrochemical performance of the tailor-made submicrostructured electrodes, cycling and rate capability experiments were performed and compared to reference bulk electrodes.

Our initial studies show promising results making these kinds of microstructured electrodes interesting for the development of new generation high power/high energy batteries.

**Figure 1: SEM micrographs of two polymer morphologies as templates for three-dimensional, interpenetrating current collectors.**

# Aqueous Li (or Na)-ion Batteries for Grid-scale Energy Storage

Yonggang Wang\* and Yongyao Xia

*Department of Chemistry and Shanghai Key Laboratory of Molecular Catalysis and Innovative Materials, Institute of New Energy, iChEM(Collaborative Innovation Center of Chemistry for Energy Materials), Fudan University, Shanghai 200433, China.*

*Address: Handan Road 220, Fudan University, Shanghai, China.*

*e-mail address: ygwang@fudan.edu.cn*

In view of the limited oil storage and the global warming threats, it has been a worldwide topic to build a low carbon society supported by sustainable energy, such as wind and solar energy. Large-scale (i.e. grid-scale) energy storage is key to integrate intermittent the renewable energy resources like wind and solar into the power grid. Therefore, it is attracting extensive attention to develop large-scale energy storage devices with high efficiency, super-long cycle life, high safety, high power density, low cost and proper energy density.<sup>[1]</sup>

In this talk, I introduce the results of our academic investigation about aqueous Li (or Na) batteries and their application in grid-scale energy storage. In 2005, we invented a new type hybrid supercapacitor in which the activated carbon (AC) was used as an anode and the Li-ion intercalated compound  $\text{LiMn}_2\text{O}_4$  was used as a cathode in an aqueous electrolyte containing Li-ions.<sup>[2,3]</sup> Then, we investigated the capacity fading mechanism of aqueous Li-ion batteries (LIBs), and developed long-life aqueous LIBs based on carbon-coated  $\text{LiTi}_2(\text{PO}_4)_3$  anode.<sup>[4]</sup> Currently, aqueous hybrid energy storage devices based on  $\text{LiMn}_2\text{O}_4$  cathode and AC/  $\text{LiTi}_2(\text{PO}_4)_3$  composite anode are being commercialized for grid-scale energy storage or stationary energy storage. Recently, we are focusing on aqueous Li-ion batteries and Na-ion batteries with a  $\text{Li}^+$  (or  $\text{Na}^+$ ) exchange membrane to separate cathode and anode, such as rechargeable Zn-Cu battery<sup>[5]</sup> and I/polymer batteries. We hope these achieved results can light on the design of high safe and low cost batteries for grid-scale energy storage.

# Surface phase transformation and $\text{CaF}_2$ coating for enhanced electrochemical performance of Li-rich Mn-based Cathodes

Xiaoyu Liu, Tao Huang, Aishui Yu\*

*Department of Chemistry, Fudan University  
220 Handan Road, Shanghai, 200433, China  
asyu@fudan.edu.cn*

To overcome the voltage decay upon cycling and increase the initial coulombic efficiency of the layered Li-rich Mn-based oxides, the double modification combining  $\text{Na}_2\text{S}_2\text{O}_8$  treatment with  $\text{CaF}_2$  coating has been first proposed in this study. The precondition  $\text{Na}_2\text{S}_2\text{O}_8$  treatment activates the  $\text{Li}_2\text{MnO}_3$  phase gently and generates a stabilized three-dimensional spinel structure on the surface of particles, leading to a suppression of surface reaction and structure conversion during the subsequent electrochemical process. The mitigation of phase transformation for  $\text{Na}_2\text{S}_2\text{O}_8$ -treated  $\text{Li}_{1.2}\text{Mn}_{0.54}\text{Ni}_{0.13}\text{Co}_{0.13}\text{O}_2$  alleviates the voltage decay and energy density degradation upon long-term charge-discharge cycling. In order to further restrain the capacity loss derived from the HF attack and manganese dissolution, 40 wt%  $\text{Na}_2\text{S}_2\text{O}_8$  treated-sample has been modified by an amorphous  $\text{CaF}_2$  layer with nano-scale thickness. The first-reported  $\text{CaF}_2$ -coated/40 wt%  $\text{Na}_2\text{S}_2\text{O}_8$  treated- $\text{Li}_{1.2}\text{Mn}_{0.54}\text{Ni}_{0.13}\text{Co}_{0.13}\text{O}_2$  presents excellent electrochemical properties with a high initial coulombic efficiency of 99.2 %, a capacity retention rate of 89.2% after 200 cycles and a high-rate capability of  $152.1 \text{ mAh g}^{-1}$  at 3C. Furthermore, A novel lithium-ion battery consisting of surface-treated  $\text{Li}_{1.2}\text{Mn}_{0.54}\text{Ni}_{0.13}\text{Co}_{0.13}\text{O}_2$  cathode and nano- $\text{Li}_4\text{Ti}_5\text{O}_{12}$  anode delivers a capacity of  $99.2 \text{ mAh g}^{-1}$  and a specific energy of  $202 \text{ Wh kg}^{-1}$  with an output voltage of 2.03 V based on the total weight of both active electrode materials. The cell also exhibits an excellent cycling stability and high-rate capability.

# Li-ion battery operation limits

Andrzej Lewandowski, Pawel Jakobczyk  
Faculty of Chemical Technology, Poznan University of Technology  
60-965 Poznan, Poland  
andrzej.lewandowski@put.poznan.pl

Operation of lithium ion-batteries, and therefore their efficiency, is limited both by thermodynamic and kinetic factors. Fact of such limits presence is usually compressed to a statement that the capacity  $q$  of the cell (or electrode material) depends on the operation rate (current). However, the capacity is a proportionality constant in the equation describing free enthalpy change,  $\Delta G$ , during cell charging/discharging:  $\Delta G = q \cdot \Delta E$  (where  $\Delta E$  is the potential change). Consequently, the postulated variation of the capacity is forbidden by the principle of maximum work:  $\Delta G = W_{\max}$ . This suggests that the  $q$  value, typically determined as the current and time product ( $q = I \cdot t$ ) must formally remain constant. Therefore, experimentally detected capacity variation as a function of operation rate (current density) reflects (i) heat generation and (ii) kinetic limits.

Heat release during Li-ion battery operation is one of the most fundamental property from the point of view of energy storage efficiency and fire safety. The irreversible heat, generated during charging and discharging,  $Q_{\text{irr}}$ , is always exothermic and is given by:  $Q_{\text{irr}} = I^2 R_s t$  (where  $I$ ,  $R_s$  and  $t$  indicate current, series resistance and time, respectively). Value of  $R_s$  can be estimated from impedance spectroscopy. Amount of energy dissipated in the form of heat increases with the operation rate which results in lowering the observed electric work – it is usually interpreted as the battery or electrode capacity decrease. If at low operating rates only 1% of energy is exchanged as a heat, increase of  $I$  value by a factor of 7 leads to  $Q_{\text{irr}}$  increase to ca. 50%. The reversible heat  $Q_{\text{rev}}$  is proportional to the entropy change,  $\Delta S$ , associated with the lithiation and delithiation of electrode materials:  $Q_{\text{rev}} = T \Delta S$ . The entropy change may be estimated from the dependence of open circuit electrode potential  $E$  on temperature  $T$ :  $\Delta S = F(dE/dT)$  in a non-isothermal cell (where  $F$  is the faraday constant).

The temperature of a cell, or a part of it, is determined by the heat balance between the amount of heat generated inside and that dissipated. When battery size increases, the ratio of heat cooling area to heat generating volume decreases, which is associated with increased fire risk. Process of temperature increase can be followed by the electrolyte decomposition reactions, with generation of gaseous products. The most commonly accepted mechanism for fire propagation proceeds via a radical generation mechanism. Exact description of processes leading to thermal runaway of Li-ion batteries is not known, but probably involves an endothermic pyrolysis of the electrolyte to form flammable gases, which then react with air and ignite. This leads to an exothermic process of flame propagation and release of additional heat amount which reinforces pyrolysis, producing free radicals at an increasing level.

The observed ‘capacity decrease’ with increasing battery operation rate may be due to kinetic reasons: (i) resistance of the SEI layer,  $R_{\text{SEI}}$  (ii) resistance of the charge transfer reaction,  $R_{\text{ct}}$  and (iii) diffusion impedance of lithium in the solid phase of the electrode material,  $Z_{\text{Li}}$  (usually expressed as the Warburg impedance). All these parameters can be determined from *ac* impedance spectroscopy curves deconvolution. Lithium diffusion impedance and low values of exchange current density seem to be the limiting processes. However, when a passivation layer is formed on the anode surface instead of the conducting SEI, it can significantly limit the battery operation rate. In the case of electrode materials which undergo drastic volume change during lithiation/delithiation (such as for example Si anode), breaking of electron conduction paths can reduce the active mass of electrode in electric contact with a current collector and strongly limit the device capacity.

# Ge@GeO<sub>2</sub> core@shell nanoparticles/multi-layer carbon composites as anode materials for lithium-ion batteries

Qi-Hui Wu<sup>1</sup>, Jinhang Hu<sup>1</sup>, Yang Yang<sup>2</sup>, Chengyuan Huang<sup>2</sup>, Hang Li<sup>1</sup>, Guoliang Chen<sup>2</sup>, Mingsen Zheng<sup>3</sup>, Qing-Biao Li<sup>1</sup>

<sup>1</sup>School of Chemistry and Life Science, Quanzhou Normal University, Quanzhou 362000, Fujian, China

<sup>3</sup>School of Chemistry and Chemical Engineering, Xiamen University, Xiamen 361005, Fujian, China  
qhwwu@qztc.edu.cn

Germanium (Ge) is one of the most promising alternative anode materials owing to its high theoretical capacity of 1600 mAh/g as formation Li<sub>22</sub>Ge<sub>5</sub> alloy [1], which is about 4 times of those of graphitic materials. Compared with silicon (Si), Ge is seldom studied because of concerns on its cost. But Ge has about 400 times higher lithium diffusivity at room temperature, 10<sup>4</sup> times higher electrical conductivity, and less significant specific volume change during lithiation/delithiation than Si [2]. These properties endue Ge to be an excellent anode material for fast charge/discharge lithium-ion batteries (LIBs). But the volume change during lithium insertion/extraction is still an impediment before Ge is commercially used in LIBs. The goal of this study is to synthesize Ge@GeO<sub>2</sub> core@shell nanoparticles/multi-layer carbon composites (Ge@GeO<sub>2</sub>/C) and then investigate their electrochemical properties as anode electrodes for LIBs. We expected that with wrap of GeO<sub>2</sub> around the Ge nanoparticles, they would show better electrochemical performance as the electrode integrity could be more easily maintained.

Fig. 1 shows the cycling performances of Ge@GeO<sub>2</sub>/C and Ge/C samples at a rate of 0.1 C (1 C = 1 A/g) for 50 cycles. The potential range is from 0.01 V to 1.5 V (vs Li/Li<sup>+</sup>). The first discharge capacities of the Ge@GeO<sub>2</sub>/C and Ge/C electrodes are very close, which are 2114.5 and 2116.7 mAh/g. The second discharge capacities for Ge@GeO<sub>2</sub>/C is 1207.0, and for Ge/C is 1311.12 mAh/g, giving the Coulombic efficiencies of 57.1% and 61.9%. The Ge/C electrode possesses the higher Coulombic efficiency at first cycle than Ge@GeO<sub>2</sub>/C probably due to the absence of reaction (1)

Compared to Ge@GeO<sub>2</sub>/C, the Ge/C electrode shows a higher capacity at the initially several cycles because of relatively high content of Ge. However, after 20 cycles, the Ge@GeO<sub>2</sub>/C electrode exhibits better capacity retentivity. At the 50<sup>th</sup> cycle, the capacities of the two electrodes are 1018.5 and 797.4 mAh/g, which indicates capacity retentions of 48.2% and 37.7% for Ge@GeO<sub>2</sub>/C and Ge/C electrodes, respectively. The GeO<sub>2</sub>@Ge/C sample presents much better cyclability than Ge/C. This may assign to its unique core@shell structure that could protect the integrity of the electrode during cycling.

Fig. 1 The cycling capabilities of Ge@GeO<sub>2</sub> core@shell/C and Ge/C composites as anode electrodes for lithium-ion batteries

Silicon, ranked as the 2nd abundant element in the earth crust, is reshaping our daily life from personal electronics (e.g. laptop, smart phone) to solar modules. The purity level of Si as a direct measure of its electronic properties, directly determines its market price varying from \$2 to thousands of dollars per kg. Electronic grade Si (EG-Si) with the highest purity of >99.9999999% (9N) is widely used in the microelectronics industry, while the solar grade Si (SG-Si) with the purity of 99.9999% (6N) is currently applied in the solar cell industry. In the lithium ion battery (LIB) area, silicon is a very promising anode material. At room temperature, 1 mole Si can alloy 3.75 mole Li delivering a theoretical capacity of 3579 mAh/g, whereas, graphite only have a theoretical capacity of 372 mAh/g.

As a cheap Si source, metallurgical silicon (MG-Si) is readily available with production rate million tons per year, which is highly attractive for applying in LIBs. MG-Si can be easily modified to form large area of porous Si nanowires (SiNW) from MG-Si through metal assisted chemical etching (MaCE) at room temperature. The unique mesoporous feature in SiNWs is created by the dissolution of metal impurities inside MG-Si. Herein we demonstrate for the first time that nanowired MG-Si can be applied as a lithium ion battery anode without any post modification (e.g. carbon or conductive polymer coating). Since inner mesoporosity well accommodate the volume expansion during the lithiation/delithiation process, MG-SiNWs show a reversible capacity of about 2111 mAh/g at a current rate of 0.2 C, an excellent stability of over at least 50 cycles (see Figure 1), as well as a good rate capability.

**Figure 1** Optical image of metallurgical silicon, TEM image of mesoporous MG-Si nanowire and the corresponding LIB performance.

## **Studies on ionic transport in liquid and polymeric electrolytes based on novel organic salts**

In spite of over thirty years of intensive studies on various types of liquid and polymeric electrolytes still there is a need for the new systems which characterized by conductivities electrochemical stabilities and safety superior to currently commercially available electrolytes. Although most of the investigations are carried out on lithium electrolytes sodium analogues seems to be equally important. One of the ways to enhance properties of the studied electrolytes is to develop new salts having relatively large anions with delocalize charge which lead to the limitation in the formation of ionic associates and in turn to the improvement in the conductivity and cation transference numbers. In the present work examples of newly developed lithium and sodium salts and their use in liquid as well as polymeric electrolytes based on low as well as high molecular weight systems will be presented.

Complementary series of crystal structures of lithium and sodium salts will be presented.. Single-crystal X-ray analysis of the salts adducts with aprotic solvents: glymes – dimethyl ethers of poly(ethylene glycols) – and crown ethers have been performed to correlate their molecular structures and properties with spectroscopic and thermal data. Comprehensive structure analysis of crystalline materials reveals valuable information about coordination ability of the studied anions and provides the basis to develop the model of poly(ethylene oxide) electrolytes and liquid systems. Presented results reveal new aggregation modes at high concentrations of lithium salts involving releasing cations by self-assembly of anionic subnetwork and shed some light on electrochemical performance of the studied anions. X-ray data are supported by FT-IR and FT-Raman studies.

In addition exemplary data of the studies of these new type electrolytes in lithium and sodium ion batteries will be presented.

# **The Benefits of Hydrothermal Flow Reactors for High Power and High Energy Lithium-ion Battery Electrode Materials**

Mechthild Luebke<sup>1,2</sup>, Zhaolin Liu<sup>2</sup>, Ian Johnson<sup>1</sup>, Jawwad Darr<sup>1</sup>

<sup>1</sup>*University College London, United Kingdom*

<sup>2</sup>*Institute of Materials Research and Engineering, Agency for Science, Technology and Research (A\*STAR), 3 Research Link, Singapore 117602, Singapore  
(mechthild.lubke.13@ucl.ac.uk)*

The clean materials technology group at UCL has developed continuous hydrothermal flow synthesis (CHFS) processes for the continuous synthesis of a range of metal oxides, sulfides and other inorganic advanced functional materials, particularly, Li ion battery electrodes. The CHFS process involves the engineered mixing of a stream of superheated water (typically at 450 °C and >22MPa) with a metal salt containing aqueous solution in the presence of various additives for both control of oxygen stoichiometry, size and shape etc. Another recent innovation in CHFS is in the successful scale-up of the process to pilot plant using a newly patented confined jet mixer, which shows tremendous promise for large scale production of nanoparticles (>1 kg/h). The modulation of process design, process scale and reaction conditions enables overall specific material properties like high levels of dopants, variation in particle size and morphology and the synthesis of composite materials.

Recently, it has been shown that these properties can be used to make high power and high energy battery electrode materials especially just via high level of dopants. Doping high levels of oxide supercapacitor transition metals into a cheap lithium-ion insertion material can improve the electronic conductivity and also drastically increase the stored charge via additional pseudocapacitive effects from the surface. On the other hand doping an alloy anode metal ion into a cheap insertion host can improve the specific capacity and also widen the operational potential window.

Exemplified, both strategies will be presented for an anatase TiO<sub>2</sub> host with a particle size of less than 7 nm and a BET surface area higher than 230 m<sup>2</sup> g<sup>-1</sup>, which is also directly suitable for scaling up. For the high power application 25 at% of niobium have been used which resulted in a specific capacity of 50 mAh g<sup>-1</sup> at an applied current of 15 A g<sup>-1</sup>. For the high energy application up to 15 at% of Sn have been used which resulted in a specific capacity of 350 mAh g<sup>-1</sup> at an applied current of 100 mA g<sup>-1</sup>.

# **In situ polyol-assisted synthesis of Zn<sub>2</sub>SnO<sub>4</sub> nanocrystals/graphene nanohybrid as high-performance anode for Li-ion batteries**

Gang Wang, Jun Peng, Yongtao Zuo, Gang Li, Feng Yu, Bin Dai, Xuhong Guo

*Email: gwangshzu@163.com*

Lithium-ion batteries (LIBs) are the power source of choice not only for popular consumer electronics but also for upcoming electric vehicles. Due to the limited capacity of graphite, many efforts have been focused on finding substitutes with larger capacity and slightly more positive intercalation voltage compared to Li/Li<sup>+</sup>, so as to reduce the possible safety problems of lithium plating. Metal oxides, typically providing a capacity more than two times larger than that of graphite with higher potential, have aroused wide interest. As an example, the theoretical capacity of SnO<sub>2</sub> can reach as high as 780 mAh g<sup>-1</sup> with the lithiation mechanism:  $\text{SnO}_2 + 4\text{Li} \rightarrow \text{Sn} + 2\text{Li}_2\text{O}$ ,  $\text{Sn} + x\text{Li} \rightarrow \text{Li}_x\text{Sn}$  ( $x \leq 4.4$ ). Recently, this strategy has been gradually expanded to ternary tin-based oxides (M<sub>2</sub>SnO<sub>4</sub>) owing largely to their unique properties emerging from electronic correlations and cooperative effects between different metal cation, which are less prominent in monometallic binary phases. However, their application in practical LIBs is still significantly hindered by the poor cyclic performance arising from poor conductivity and huge volume expansion during charge/discharge.

Graphene (GR) has a large specific surface area, excellent conductive, mechanical, and hydrophobic properties and is chemically stable, making it an ideal support. Fabrication of graphene/metal oxide composites is expected to be an effective and practical method to resolve these problems. From the viewpoint of structure, on one hand, metal oxides anchored or dispersed on GR not only suppress the agglomeration and restacking of GR but also increase the available surface area of the GR alone, leading to high electrochemical activity. On the other hand, GR as a support of metal oxides can induce the nucleation, growth and formation of fine metal oxide nano-/microstructures with uniform dispersion and controlled morphology on the surface of graphene with high chemical functionality. The final graphene-supported metal oxide can form a perfect integrated structure with a developed electron conductive network and shortened ion transport paths. Significant synergistic effects often occur in graphene/metal oxide composites because of size effects and interfacial interactions. However, in situ growth of metal oxide nanocrystals, especially multi-cationic metal oxides nanocrystals, on the surface of GR sheets still be difficult to achieve.

Zinc stannate (Zn<sub>2</sub>SnO<sub>4</sub>), a cubic inverse spinel structured A<sub>2II</sub>B<sub>IV</sub>O<sub>4</sub> compound (space group Fd3m), is well known for its high electron mobility, high electrical conductivity. Therefore, Zn<sub>2</sub>SnO<sub>4</sub> represents a promising material for application as an anode material in lithium ion batteries. Herein, we report a facile one-pot in situ polyol-assisted hydrothermal route to prepare Zn<sub>2</sub>SnO<sub>4</sub> nanocrystals/graphene (Zn<sub>2</sub>SnO<sub>4</sub>/GR) nanohybrid. The Zn<sub>2</sub>SnO<sub>4</sub> nanocrystals (5-10nm) are uniformly dispersed and immobilized by the graphene nanosheets reduced from GO. The electrochemical tests showed that the Zn<sub>2</sub>SnO<sub>4</sub>/GR hybrid exhibits an obviously improved electrochemical performance compared with bare Zn<sub>2</sub>SnO<sub>4</sub>, indicating its promising application as anode for Li-ion batteries.

# Hybridization of graphene sheets and carbon-coated Fe<sub>3</sub>O<sub>4</sub> hollow nanoparticles as a high-performance anode material for lithium-ion batteries

Gang Wang, Yongtao Zuo, Jun Peng, Gang Li, Feng Yu, Bin Dai, Xuhong Guo

School of Chemistry and Chemical Engineering, Key Laboratory for Green Processing of Chemical Engineering of Xinjiang Bingtuan, Shihezi University, Shihezi 832003, P.R. China

Email: gwangshzu@163.com

In order to meet the increasing requirements for electric vehicles (EVs) and hybrid electronic vehicles (HEVs) applications, significant achievements have been gained in the research of anode materials with superior capacity for lithium-ion batteries (LIBs), such as Si, Sn and transition metal oxides. Among these potential anode materials, Fe<sub>3</sub>O<sub>4</sub> shows high theoretical capacity (928 mAh g<sup>-1</sup>), low cost, eco-friendliness, and natural abundance, thus has attracted considerable attention. However, its large volume expansion/contraction and severe particle aggregation associated with the Li<sup>+</sup> insertion and extraction process lead to electrode pulverization and loss of interparticle contact and, consequently, result in a large irreversible capacity loss and poor cycling stability.

A variety of appealing strategies have been utilized to solve these intractable problems, including the use of carbon-based nanocomposites and various Fe<sub>3</sub>O<sub>4</sub> nanostructures/microstructures. However, to keep large reversible capacity combined with high Coulombic efficiency, achieving long cycling life and good rate capability of Fe<sub>3</sub>O<sub>4</sub> electrode material still remains a great challenge. Recently, a new type of nanoarchitecture, a hollow structure together with carbon coating, was proposed and it manifests improved cycling performance and rate capability. To circumvent the challenges faced by inner-pore filling or exterior coating, a flexible confining structure is expected to provide enough buffer space for improving the cycling stability of anode materials by reducing the pulverization.

Graphene, a new two-dimensional carbon material, is recently expected to be an advanced anode material in LIBs due to its superior electrical conductivity, high surface-to-volume ratio, ultrathin thickness, structural flexibility, and chemical stability. More importantly, graphene can also be used in composites with metal oxide nanoparticles (NPs) to improve the electrochemical performance of these particles because the ultrathin flexible graphene layers not only can provide a support for anchoring well-dispersed NPs and work as a highly conductive matrix for enabling good contact between them but also can effectively prevent the volume expansion/contraction and aggregation of NPs during Li charge/discharge process. Therefore, we take the advantages of the characteristics of graphene to construct two-dimensional Fe<sub>3</sub>O<sub>4</sub>@C/graphene composites, uniting the two building blocks for reducing the pulverization of these materials and enhancing their cycling stability, as well as inhibiting the degree of restacking of graphene (Scheme 1). First, the Fe<sub>3</sub>O<sub>4</sub>/graphene hybrids were synthesized via a facile, one-step solvothermal approach by the in situ conversion of FeCl<sub>3</sub> to Fe<sub>3</sub>O<sub>4</sub> and simultaneous reduction of GO to graphene in ethylene glycol. Then, carbon shells were coated onto Fe<sub>3</sub>O<sub>4</sub> NPs by dispersing the Fe<sub>3</sub>O<sub>4</sub>/graphene hybrids in glucose aqueous solution for hydrothermal treatment. It is found that the Fe<sub>3</sub>O<sub>4</sub>@C/graphene composite has the advantages of the two building blocks and exhibits a large reversible capacity, enhanced cyclic stability, and excellent rate capability.

Scheme 1 Schematic representation of the fabrication process of Fe<sub>3</sub>O<sub>4</sub>@C/graphene composite

# Enabling Catalytic Oxidation of $\text{Li}_2\text{O}_2$ at Liquid-Solid Interface: A Successful Evolution for an Aprotic Li-O<sub>2</sub> Battery

Ping He

College of Engineering and Applied Sciences, National Laboratory of Solid State Microstructures,  
Nanjing University, Nanjing, Jiangsu, 210093, PR China  
Pinghe@nju.edu.cn

As we know, rechargeable lithium-O<sub>2</sub> batteries, especially in organic aprotic electrolyte, have attracted much worldwide attention due to its high theoretical energy density of 3450 Wh kg<sup>-1</sup> (including lithium and oxygen). However, for the aprotic Li-O<sub>2</sub> battery, the insulating discharge product  $\text{Li}_2\text{O}_2$  is accumulated and blocked the porous cathode gradually, which results in the high charging voltage, leading to the low round-trip efficiency, poor cycle life and even detrimental electrolyte decomposition. As seen in **Figure 1**. A novel strategy based on redox mediators as the soluble oxidation catalyst has been proposed to reduce the charge overpotential.<sup>[1-3]</sup> TEMPO<sup>+</sup>/TEMPO redox couple has dramatically reduced the charge voltage of  $\text{Li}_2\text{O}_2$  oxidation and promote the round-trip efficiency of this battery system. The soluble catalyst transfer solid/solid interfacial electrochemical reaction to solution/solid interfacial chemical oxidation, which indeed provides significant evolution for aprotic Li-O<sub>2</sub> battery. In this report, we highlight the work concerning the soluble catalyst of TEMPO and summarized the fundamental criteria of the suitable redox mediators as mobile OER catalyst. Meanwhile, we develop another new redox couple, 10-methyl-10H-phenothiazine (MPT), as soluble catalyst in aprotic Li-O<sub>2</sub> battery.<sup>[4]</sup> Its formal redox potential of 3.67 V vs. Li<sup>+</sup>/Li makes it a promising redox candidate. The overpotential with MPT redox mediator is 800 mV, which far below that of without MPT in non-aqueous Li-O<sub>2</sub> battery. At the end of our report, we also propose some challenges and disadvantage of soluble catalyst using in aprotic Li-O<sub>2</sub> battery.

Figure 1. The proposed catalytic mechanism of the OER with a suitable redox mediator as the soluble catalyst in an aprotic Li-O<sub>2</sub> battery.

# Studies of Non-metal Elements Doped Carbon Coated Electrode Materials of Lithium (Sodium) Ion Batteries

Haimei Liu, Cong Wang, Wei Shen

College of Environmental and Chemical Engineering, Shanghai University of Electric Power,  
Shanghai 200090, China

e-mail :liuhm@shiep.edu.cn

State Key Laboratory of Chemical Resource Engineering, Beijing University of Chemical Technology,  
Beijing 100029, China

Carbon coating is a low cost and high-efficiency modification approach which is widely used to modify various lithium ion batteries electrode materials<sup>[1]</sup>, such as  $\text{LiFePO}_4$ ,  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ ,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ , etc. Nowadays, non-metal elements doping, such as N or B doping<sup>[2,3]</sup>, are widely adopted on carbon-based materials and exhibited obvious modification effects. Based on the above analyses, a novel modification approach, non-metal elements doped carbon coating, has been proposed in this work. In this work, N- and B-doped carbon coating has been used to improve the electrochemical performances of  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ <sup>[4,5]</sup>, compared with pure carbon coating, these two non-metal elements doped carbon coating approaches exhibited more obvious modification effects on  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ .

**Fig. 1** (a) XRD patterns, (b) XPS spectra, (c) HRTEM images and (d) rate stability for LVP/C+N.

XRD patterns of N-doped carbon coating  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$  (LVP/C+N) indicate that N-doped carbon coating make no effects on the structure of  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ . As shown in Fig. 1b, N is successfully doped in carbon coating layer of  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ ; there is an uniform and complete carbon layer on the surface of LVP/C+N particles (Fig. 1c), therefore, compared with LVP/C, LVP/C+N shows much better rate stability.

**Fig. 2** (a) XRD patterns, (b) XPS spectra, (c) distribution diagram and (d) rate stability for LVP/C+B.

Based on XRD patterns in Fig. 2, moderate B-doped carbon coating make no effects on the structure of  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ . As shown in Fig. 1b, B is successfully doped in carbon coating layer of  $\text{Li}_3\text{V}_2(\text{PO}_4)_3$ ; there are four doping types:  $\text{BC}_3$ ,  $\text{BC}_2\text{O}$ ,  $\text{BCO}_2$ ,  $\text{B}_4\text{C}$  existed in LVP/C+B. These four doping types has different distributions in LVP/C+B. Compared with LVP/C, LVP/C+B shows much better rate performance.

Moreover, the N-doped carbon coating modification approach are also used to improve the electrochemical properties of  $\text{Na}_3\text{V}_2(\text{PO}_4)_3$  sodium ion batteries electrode material. Based on the test results of XPS, N element is successfully doped in the carbon layer of  $\text{Na}_3\text{V}_2(\text{PO}_4)_3$ , which further improve the electronic conductivity and defect level of carbon coated layer.

# Temperature Effects on Porous $\text{ZnCo}_2\text{O}_4$ Anode for Lithium-ion Batteries

Ji-Xuan Fu, Wei-Ting Wong and Wei-Ren Liu\*

Department of Chemical Engineering, Chung Yuan Christian University, Chung Li District, Taoyuan City, Taiwan

Correspondence: WRLiu1203@gmail.com

Herein,  $\text{ZnCo}_2\text{O}_4$  is synthesized via hydrothermal method with different annealing temperature [1]. X-ray diffraction (XRD), Brunauer-Emmett-Teller (BET), scanning electron microscopy (SEM) are used to study the structure and characteristics of the obtained powders. Thermogravimetric analysis (TGA) of the precursors is also carried out in this study. The morphology of  $\text{ZnCo}_2\text{O}_4$  turns to sphere-like with porous structure when the annealing temperature as high as 600 °C (Figure 1). The as-prepared porous  $\text{ZnCo}_2\text{O}_4$  nanospheres synthesized at 600 °C have been applied as anode materials of Li-ion batteries, the initial discharge capacity is 1800.4 mAh/g. After 30 cycles, the capacity still retain 1242.2 mAh/g (Figure 2). The AC data shows that the  $\text{ZnCo}_2\text{O}_4$  nanospheres have lower surface layer resistance. The porous nanostructures and large surface area are responsible for superior performance. Moreover, it is indicated that porous  $\text{ZnCo}_2\text{O}_4$  nanospheres synthesized at 600 °C show larger capacity and better performance than 500 °C and 700 °C, because of their more complete structure.

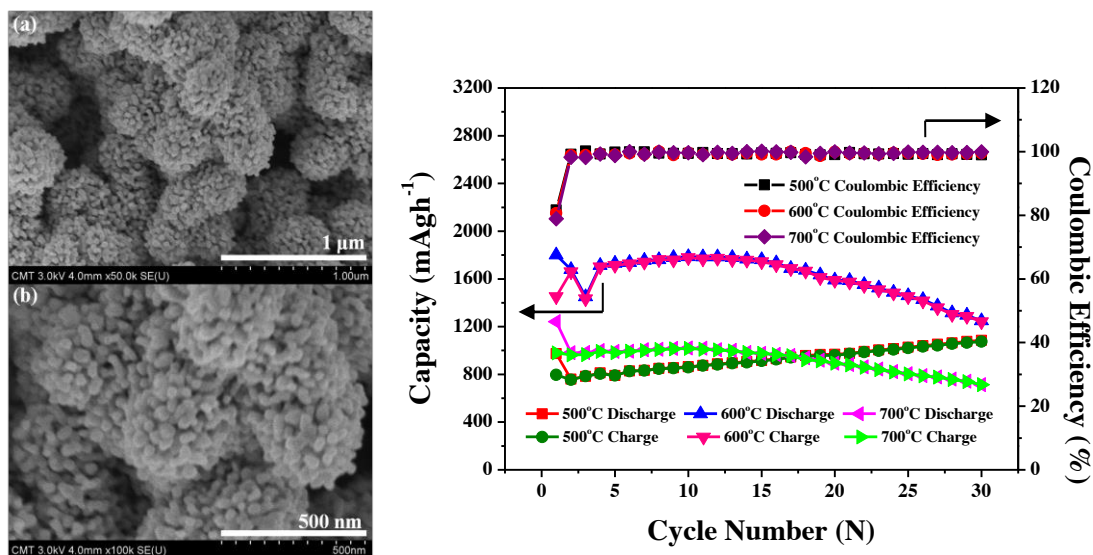

Figure 1 SEM images of  $\text{ZnCo}_2\text{O}_4$  synthesized at 600 °C: (a) low magnification; (b) high magnification.

Figure 2 Cycle performance of  $\text{ZnCo}_2\text{O}_4$  synthesized at 500 °C, 600 °C and 700 °C.

Tel: +886-3-265-4140; fax: +886-3-265-4199

The Li-rich layered cathode materials,  $\text{Li}_{1.2}\text{Ni}_{0.4-x}\text{Al}_x\text{Mn}_{0.6}\text{O}_{2.2-y}\text{Cl}_y$  ( $0 \leq x \leq 0.03$  and  $0 \leq y \leq 0.03$ ), were successfully synthesized from a co-precipitation precursor at 900 °C in air. The influence of  $\text{Al}^{3+}$ - $\text{Cl}^-$  co-substitution on the morphology, structure and electrochemical performance was characterized by X-ray diffraction (XRD), scanning electron microscope (SEM), X-ray photoelectron spectroscopy (XPS), transmission electron microscopy (TEM) and electrochemical and charge–discharge cycling. Via doping Al/Cl ions in the cathode, the electrochemical performance could not only be enhanced in room temperature but also quite well in high working temperature of 55 °C. The as-synthesized optimal-composition of  $\text{Li}_{1.2}\text{Ni}_{0.37}\text{Al}_{0.03}\text{Mn}_{0.6}\text{O}_{2.17}\text{Cl}_{0.03}$  deliver reversible capacity of 176 mAh/g and coulombic efficiency was 84.31% at the 23th cycle. For 55 °C test, the discharge capacity demonstrates a very good capacity of as high as 206 mAh/g and capacity loss rate was only 0.95 mAh  $\text{g}^{-1}$  cycle<sup>-1</sup> at the 21th cycle. Figure 1 shows that the differential capacity vs. voltage plots derived from the cycling curves at 55 °C. We find that the  $\text{Al}^{3+}$ - $\text{Cl}^-$  co-doped materials reduction peaks change were smaller than those of undoped materials during 20th cycle, and lithium ions are extracted and inserted into the layered phase by one-step process. The  $\text{Al}^{3+}$ - $\text{Cl}^-$  co-substitution enhanced structural stability by formation of strong Mn–Cl and Ni–Cl bonds revealed by XPS analysis[1]. Moreover, the  $\text{Al}^{3+}$ - $\text{Cl}^-$  co-doped materials was increased by 33.32% and impedance was reduced by 52.17% compared to bare sample.

Figure 1 Differential capacity vs. voltage of  $\text{Li}_{1.2}\text{Ni}_{0.4-x}\text{Al}_x\text{Mn}_{0.6}\text{O}_{2.2-y}\text{Cl}_y$  cells cycled at 2.0–4.6 V. (a)  $\text{Li}_{1.2}\text{Ni}_{0.4}\text{Mn}_{0.6}\text{O}_{2.2}$ , (b)  $\text{Li}_{1.2}\text{Ni}_{0.37}\text{Al}_{0.03}\text{Mn}_{0.6}\text{O}_{2.17}\text{Cl}_{0.03}$ . (●) First cycle, (▲) 5th cycle, (○) 10th cycle and (Δ) 20th cycle.

# Binder Effects and Architecture Design of Si-based Composite Anode for Li-ion batteries

Yu-Chian Shie, Jeng-Shin Lu and Wei-Ren Liu \*

Department of Chemical Engineering, Chung Yuan Christian University, Chung Li, Taiwan

\*E-mail address: [WRLiu1203@gmail.com](mailto:WRLiu1203@gmail.com) (W. R. Liu)

Tel: +886-3-265-4140; fax: +886-3-265-4199

Si-based anodes in lithium ion batteries (LIBs) offer exceptionally high theoretical capacity, but it has dramatic volume change during lithiation/delithiation processes which typically leads to rapid anode degradation. Here we designed a facile and self-assembly strategy to construct three dimensional (3D) polymeric network as a promising binder for high-performance Si-SiC recovered the waste slurry from solar panels anodes through in-situ interconnecting alginate chains by additive divalent cations,  $\text{Sr}^{2+}$ ,  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ . The highly cross-linked alginate network allows superb mechanical property and strong interactions, which can restrain the dramatic volume. The affinity of alginate chains respect to divalent ions decreases in the following order:  $\text{Sr}^{2+} > \text{Ca}^{2+} > \text{Mg}^{2+}$  [1]. The structure and surface morphology of the composite were carried out by XRD, FE-SEM, viscometer and FTIR and electrochemical analysis were also performed to investigate the effect of the operating parameters. The viscosity became larger by additive divalent cations. (Figure 2) As a result, it has prolonged cycle life and less impedance by the highly cross-linked alginate network with  $\text{Sr}^{2+}$ . The retention still has 80% after 100 cycles.(Fig. 2)

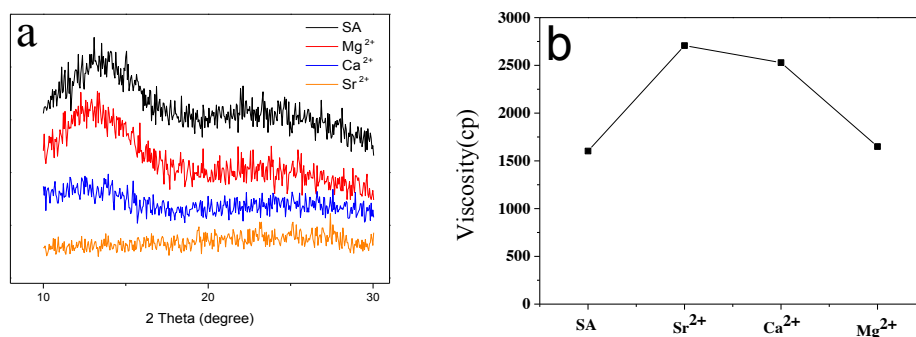

Figure 1 Preparation of binder added different divalent cations: (a) XRD patterns; (b) viscosity measurement.

An environmental-friendly and highly efficient Sn-based anode materials were synthesized via a green process for use in lithium-ion batteries and showed high energy densities, good cycle life performance and a decrease in cost and safety hazards.

This new material has been developed based on the nano-sized Cu seeds which act as the nuclei for well dispersion of the thermally reduced Sn and provide an internal anchoring function to depress growth of Sn particles resulting from its higher melting point compared to pure Sn during thermal reaction. Besides that, the purging gas during high temperature sintering which not only reduce tin metal but also prolong the cycle life of the composite material.

The results showed that the first discharge capacity was 1225 mAh/g as well as the first cycle columbic efficiency was 80%, and the capacity retention was 84% after 30 cycles. Under a 200 mA/g current density cycling, the first discharge capacity was 1131 mAh/g as well as first cycle columbic efficiency was 87%, and the capacity retention was 80% after 200 cycles.

## 1. Introduction

With regard to the remarkably growing market for electric vehicles (EVs), hybrid electric vehicles (HEVs) and stationery energy storage applications in recent years, development of larger lithium ion battery (LIB) systems with high performance and low price is urgently required. To match the requirement, we have successfully developed fiber-type electrodes for LIBs without using any binders and conductive agents.<sup>1,2</sup> However, a predoping process is necessary to apply the battery using fiber-type electrodes, making it impractical. To extend the previous research works, this study therefore focuses on the development of LIBs using the fiber-type electrodes, which can be applied without any predoping process.

## 2. Experimental

To prepare the fiber-type cathode, a carbon fiber tow containing 12,000 single fibers was used as the current collector matrix. The fiber tow was electrodeposited a Mn-O layer in an  $\text{Mn}(\text{NO}_3)_2$  solution, followed by a hydrothermal treatment at 110°C for 20 h, in which LiOH solution was used as the reaction solution. The hydrothermally treated fibers were further rinsed by deionized water and dried in a vacuum atmosphere at 160 °C for 6 h, then the fiber-type Li-Mn-O cathode can be obtained. A coin-type test cell (R2032), containing the fiber-type cathode and carbon fiber anode, was used to carry out the galvanostatic charge/discharge experiments. The electrolyte used in the test cells was 1 M  $\text{LiPF}_6$  in a mixture of ethylene carbonate (EC) and diethyl carbonate (DEC) at the ratio of 1:1 (v/v).

## 3. Results and Discussion

Fig. 1 shows the morphologies of the original carbon fiber (a) and the typical as-prepared fiber-type cathode (b). The untreated carbon fiber retains its smooth surface without any contamination or defects, thus providing a favorable surface for the synthesis reaction. After the hydrothermal reaction, a layer consisted of nanoparticles was coated on the carbon fiber in a random and loose manner, bearing a number of void space. Fig. 2 shows the cycle performance and its coulomb efficiency of a full cell using the fiber-type cathode and carbon fiber anode. The capacity slightly decreased from 125 to 100 mAh/g at the 30th cycle; while its coulomb efficiency tends to be stable at a value of 95%, except for the first cycle. The high coulomb efficiency indicated that both the cathode and anode materials are favorable hosts for lithium ions to reversibly intercalate/deintercalate.

In the past, the capacity enlargement by a lot of Sn composites modification has been widely attractive. However, less attention has been focused on the effect of Sn composites on the reaction between carbon substrate and electrolyte. This issue is noteworthy since the carbon matrix is the major anode substrate for lithium ion batteries (LIBs). Although the anode capacity of LIBs was greatly raised by nano-sized Sn modification on carbon substrate, it is difficult to find out the effect on the carbon matrix caused by the Sn composites [1]. So, in this study, we try to fabricate the carbon anode with relatively less Sn composites modification by chemical modified and pyrolysis methods to highlight the influence of the Sn composites on the carbon matrix.

Nano-tin composites on graphite materials can be obtained through a simple chemical reaction between  $\text{Sn}(\text{BF}_4)_2$  and  $\text{Na}_2\text{S}_2\text{O}_4$  in aqueous solution and converted to  $\text{SnO}_2$  after pyrolysis. The size of nano-tin composites is around 14.7 nm. The graphite anodes with Sn-based nanocomposites show a capacity retention over 97.3% after 50 cycles, as shown in Fig. 1. As can be observed in Fig. 2, the original IR peaks at 2826 and 2988  $\text{cm}^{-1}$  shift to 2855 and 2935  $\text{cm}^{-1}$ , which are attributed to the  $\nu(\text{CH}_2)$  in  $(\text{CH}_2\text{OCO}_2\text{Li})_2$  [2,3], after the modification with Sn-based composites. The spectral results provide the evidence that the presence of Sn-based composites on the graphite surface can inhibit the reaction of  $(\text{CH}_2\text{OCO}_2\text{Li})_2$  with HF to protect the carbon surface from electrolyte decomposition and improve the cycling performance in LIBs.

Fig. 1 Cycling performance of the pristine (black), the pre-modified (blue), and the annealed (red) graphite anodes.

Fig. 2 IR spectra of the pristine (black), the pre-modified (blue), and the annealed (red) graphite anodes after cycling test.

Lithium titanate defect spinel ( $\text{Li}_4\text{Ti}_5\text{O}_{12}$ ) is one of the most promising anode materials for lithium ion batteries (LIBs) because its negligible volume change and stable operating voltage during charging/discharging. However, the intrinsic insulating property of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  hinders its high power applications. Compositing and nanonization are two approaches to overcome this drawback. The former enhances the external electrical conductivity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ , while the latter shortens the length of diffusion during charging/discharging. In this work,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  defect spinel anode nanoparticles were synthesized via a modified reaction under autogenic pressure at elevated temperature (RAPET) technique. Unlike the conventional white  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  powders, blue  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  nanoparticles were fabricated. The microstructures and electrochemical properties, namely cycle performance and rate capability of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  nanoparticles were examined. In addition, *ab initio* calculations based on density function theory (DFT) were performed to clarify the enhanced electrochemical properties of the  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  defect spinel. The formation mechanism of the  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  nanoparticles as well as the origin of superior electrochemical properties is elaborated in this paper.

Figure 1. Total density of states (DOS) of (a) the pristine  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  and (b) the reduced  $\text{Li}_4\text{Ti}_5\text{O}_{11.875}$ , where the Fermi energy was aligned to 0 eV in the energy scale.

# ***Ab initio*-aided $\text{Li}_4\text{Ti}_5\text{O}_{12}$ defect spinel electrode materials designs for durable lithium ion batteries**

Shih-kang Lin<sup>a,b,c,d</sup>, Ping-chun Tsai<sup>a</sup>, and Wen-Dung Hsu<sup>a,b,c</sup>

<sup>a</sup>Department of Materials Science and Engineering, National Cheng Kung University, Tainan 70101, Taiwan; <sup>b</sup>Promotion Center for Global Materials Research, National Cheng Kung University, Tainan 70101, Taiwan; <sup>c</sup>Research Center for Energy Technology and Strategy, National Cheng Kung University, Tainan 70101, Taiwan; <sup>d</sup>Center for Micro/Nano Science and Technology, National Cheng Kung University, Tainan 70101, Taiwan

To meet the great demands of reliable and durable energy-storage systems for the “smart-grid society”, lithium ion batteries (LIBs) with better efficiency, stability, and safety are required. The  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  (LTO) defect spinel is the most promising anode materials for long-life LIBs because of its merits of negligible volume changes ( $\sim 1\%$ ) and stable operating voltage during charging/discharging. The volume changes of LTO are more than ten times less than the conventional graphite materials (10%) and much less than various Si (400%) and alloy materials. However, the insulating property of LTO that results in poor rate capability limits its range of power-oriented applications. Doping transition metals is a commonly seen strategy to enhance electrical and electrochemical properties of LTO. However, the general trend for doping-induced effects on LTO is unclear. In this work, *ab initio* calculations are performed to study the phase stability, electronic structures, and electrochemical properties of the transition metal M-doped LTO ( $\text{Li}_4\text{M}_{0.125}\text{Ti}_{4.875}\text{O}_{12}$ ). In addition, an attempt was made to explore new 4-5-12 defect spinel other than the known  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  and  $\text{Li}_4\text{Mn}_5\text{O}_{12}$  defect spinel. The class of the  $\text{Li}_4\text{Me}_5\text{O}_{12}$  defect spinel with the framework of  $[\text{Li}_{1/3}\text{Me}_{5/3}]_{16d}(\text{O}_4)_{32e}$  was investigated. With the aid of *ab initio* calculations, general trends of doping-induced physical property changes, such as the changes of lattice parameters, phase stabilities, average operating voltages, and electrical properties, were revealed. All M-doped LTO showed high structural stability during charging/discharging, indicating the excellent cyclability and high safety of LTO remains for the M-doped LTO. Nevertheless, doping significantly affects the electronic structure of LTO. The desired dopant for the M-doped LTO and potential “nature’s missing 4-5-12 defect spinel” as anode materials in LIBs is proposed.

Keywords: Li ion battery;  $\text{Li}_4\text{Me}_5\text{O}_{12}$ ; *ab initio* calculation; defect spinel

Figure 1. Full supercell models of (a)  $\text{Li}_{32}\text{Ti}_{40}\text{O}_{96}$  for the  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  phase and (b)  $\text{Li}_{56}\text{Ti}_{40}\text{O}_{96}$  for the  $\text{Li}_7\text{Ti}_5\text{O}_{12}$  phase.

High energy mechanical milling (HEMM) is known as a cheap, facile and scale-up way to reduce powder size and induce amorphization and alloying under non-equilibrium. In this work, silicon powders  $\text{Si}_\text{H}$ ,  $\text{Si}_\text{W}$  and  $\text{Si}_{\text{H+W}}$  were prepared by HEMM, wet milling and combined HEMM and wet milling from pristine silicon,  $\text{Si}_\text{P}$ , (D50 ~10  $\mu\text{m}$ ). Tackled powders were investigated as anode materials for Li-ion batteries. Upon HEMM, pristine silicon powder processed repeatedly cold welding and fracturing and formed micrometric silicon aggregate (D50 ~5  $\mu\text{m}$ ) constructed by cold welded submicrometric particles after HEMM 9 hrs for  $\text{Si}_\text{H}$ .  $\text{Si}_\text{H}$  showed the nanocrystallite embedded in amorphous region confirmed by TEM. Randomly Nanocrystalline/amorphous interface assumed to provide additional path for Li ion diffusion. However, secondary hard agglomeration caused by cold welding hindered this benefit and speed up crumbling of the agglomerate reflecting on poor cyclic performance compared to reduced  $\text{Si}_\text{W}$  (D50 ~0.4  $\mu\text{m}$ ) of discrete primary particle. The agglomeration broke along interfaces of welded primary particles by further wet milling for  $\text{Si}_{\text{H+W}}$  and reduced the secondary particle size (D50 ~0.3  $\mu\text{m}$ ). It significantly improved the cyclic performance during discharge-charge process compared to  $\text{Si}_\text{H}$  and  $\text{Si}_\text{W}$ .

Fig. Cycling performance of  $\text{Si}_\text{P}$ ,  $\text{Si}_\text{H}$ ,  $\text{Si}_\text{W}$  and  $\text{Si}_{\text{H+W}}$  conducted at current density 200 mA/g between 0.02 V to 1.5 V.

# Near-Field Optical Spectroscopy and Imaging of the SEI Layer on Sn, Si and Graphite Li-ion Anodes

Robert Kostecki, Maurice Ayache, Simon Lux, Ivan Lucas  
Lawrence Berkeley National Laboratory,  
Berkeley, CA, 94720 United States  
r\_kostecki@lbl.gov

Most Li-ion battery systems operate beyond the thermodynamic stability limits of the electrolytes. Reactions between positive and negative electrodes and the electrolyte result in the formation of new phases and interphases, which hinder further electrolyte decomposition and assure battery operation over the lifespan of the application. Fundamental investigations of the electrode material properties of electrochemical systems are essential for improvements in electric energy storage technologies<sup>1</sup>. Among the most critical aspects of Li-ion battery operation is the solid electrolyte interphase (SEI) layer<sup>2</sup>, which forms at the negative electrode surface due to the electroreduction of the electrolyte during initial charge/discharge cycles<sup>3,4</sup>. This highly inhomogeneous, ionically conductive and electrically resistive film prevents further electrolyte decomposition at the electrode surface and assures long-term operation of Li-ion battery cells. The chemical composition and functional mechanism of the SEI are not well understood, due to the technical barriers associated with characterization methodologies across length and temporal scales that correspond to the SEI basic components and processes.<sup>5</sup>

The requirements for long-term stability of Li-ion batteries are extremely stringent and necessitate control of the chemistry at a wide variety of temporal and structural length scales. This presentation provides an overview of infrared apertureless near-field scanning optical microscopy (IR aNSOM) as a valuable emerging tool in the chemical characterization of interfacial layers at the nanometer scale in electrochemical systems. This work demonstrates an IR aNSOM study of the SEI layer, on a model Sn, Si and graphite electrodes. IR aNSOM images recorded at several wavelengths reveal significant chemical contrast variations tied to specific topographic features and distribution of lithium carbonate and lithium ethylene dicarbonate on the sample surface.

Due to energy crisis and environmental pollution caused by limiting fossil fuels and their waste emissions, much effort has been put in on the topic of sustainable, renewable and clean energy alternatives such as solar and wind energy. However, due to the intermittent and uncontrollable nature of these resources, it might lead to the fluctuation of electricity distribution and causing damages to traditional grids. Therefore, energy storage systems are needed to store these energies and maintain the quality of the grids. Vanadium flow battery is one of the potential candidates since it's advantageous in decouplization of energy and power density, deep charge-discharge ability, long cycle life, etc. However, it suffers severe crossover, slow reaction kinetics and low reversibility of vanadium ions that prohibit its commercialization and general usage. In our study, we proposed a facile method to improve the disadvantages by forming amorphous carbon layers on the carbon felt electrodes. The functional groups and defects on the surface of electrodes might offer more active sites for vanadium ions and promote the kinetics and reversibility of the redox reaction. Surface analysis and electrochemical measurements were conducted to study the mechanisms and confirm the results we observed.

# Investigation of surface and bulk structural modifications in Li/Mn-rich cathode materials of Li-ion batteries using X-ray absorption spectroscopy

Li/Mn-rich ‘layered-layered’ cathode materials (LMR) with the general formula  $x \text{Li}_2\text{MnO}_3 \cdot (1-x) \text{LiMO}_2$  (M=Mn, Co, Ni; typically:  $x=0.5$ ) provide very high, reversible discharge capacities above  $200 \text{ mAh g}^{-1}$  at a high average potential of around  $3.75 \text{ V vs. Li/Li}^+$ . For this reason, this material class is of major academic and commercial interest, as its commercialization would result in a boost in energy density for secondary lithium batteries.[1,2] Despite their highly promising electrochemical properties,[3] LMR-oxides to date still face numerous challenges, such as insufficient cycling stability and the decay of the operating voltage upon prolonged cycling in a wide voltage range (‘voltage decay’).[4] Most X-ray absorption spectroscopy (XAS) studies on cathode materials are carried out in transmission mode, which provides local structural information of the bulk material.[5] However, the material surface is also of great interest, as it stands in direct contact with the highly oxidizing electrolyte. For this purpose, Oxygen K-edge Near-Edge X-ray absorption fine structure (NEXAFS) measurements were carried out in the total electron yield mode (Fig.1). As it can be seen, the data of the pristine state resembles that of the discharged (re-lithiated) state at  $2.5 \text{ V}$ , while the charged (de-lithiated) states of the 1<sup>st</sup> and 2<sup>nd</sup> cycle resemble one another. These results indicate reversible structural changes taking place also at the material surface.

**Figure 1:** Normalized O K-edge NEXAFS data of LMR cathodes  
 a)  $\text{Li}_{1.2}\text{Mn}_{0.4}\text{Co}_{0.2}\text{O}_2$  b)  $\text{Li}_{1.2}\text{Mn}_{0.56}\text{Ni}_{0.16}\text{Co}_{0.08}\text{O}_2$  and c)  $\text{Li}_{1.2}\text{Mn}_{0.4}\text{Co}_{0.4}\text{O}_2$   
 in the indicated states of charge.

## **Abstract**

Lithium iron phosphate (LFP) has attracted tremendous attention as a next-generation electrode material in lithium rechargeable batteries for large scale energy storage systems due to the use of low-cost iron and chemical/electrochemical stability. While the lithium diffusion in LFP, the essential property in battery operation, is relatively fast due to the one-dimensional tunnel present in the olivine crystal, the tunnel is inherently susceptible to immobile anti-site defects which, if any, block the lithium diffusion and lead to the inferior performance. Herein, we demonstrate that the kinetic issue arising from the defects in LFP can be completely eliminated in a new olivine LFP, which we successfully synthesized for the first time. The doping in the olivine structure reduces the concentration of defects in the tunnel by 7 orders of magnitude. Moreover, it opens up a new lithium diffusion path along the [101] direction making the olivine LFP as a three-dimensional lithium diffuser. We also find that the intrinsic energy barrier for phase transition gets notably lower in the lithium excess olivine LFP. The fundamentally different nature of the new olivine than normal LFP additionally induces faster charging capability, lowering thermal solid-solution temperature and less memory effect.

Rice husks (RHs) are the natural sheaths that form on rice grains during their growth and are removed as waste during processing the grains. Husks have no commercial value and are normally combusted openly, thereby causing environmental pollution and disposal problems. After calcination, RHs produced of about 20% ash of which 90% was silica. Silica is the major inorganic constituent of the rice husk, and by carrying out an acid chemical treatment followed by the process of burning, it is possible to extract high-surface area amorphous silica. In this work, nanosilica was prepared from the rice husks derived amorphous silica by sol-gel method. The optimal preparation conditions for the preparation of silica nanoparticles were obtained and the as prepared silica nanoparticles were characterized by x-ray diffraction (XRD), scanning electron microscopy (SEM), transmission electron microscopy (TEM), Fourier Transform Infra Red (FTIR) Spectroscopy and x-ray photoelectron spectroscopy (XPS). The XRD analysis indicated the amorphous structure of the prepared silica nanoparticles while the SEM and TEM images exhibited mono dispersed nano sized silica particles. Nanosilica were then tested as anode materials for lithium ion batteries using cycle tests and cyclic voltammetry. Cycle tests showed that a stable cycling until the 50<sup>th</sup> cycle was demonstrated by rice husk based nano silica particles with a high initial coulombic efficiency.

## **Abstract**

The structure change of commercial polypropylene/polyethylene/polypropylene (PP/PE/PP) trilayer micro-porous film, used as a separator of lithium ion batteries (LIBs), undergo different charging-discharging current densities was investigated by means of *in-situ* X-ray diffraction (XRD). The unpredictable nanoscale crystalline structure change of both PP and PE are discovered during charging process. The embedded lithium ions is supposed to be the main cause to the increasing of lattice space. Especially in the PP(040) phase, the maximum extended spacing ( $\Delta d/d_0$ ) of 1.54%, in contrast to it before charging, is found after the LIBs is fully charged; while other phases usually has  $\Delta d/d_0$  less than 0.5%. No other phases has the effect as evident as PP(040) phase. That means the behavior is selective. We also found that the structure cannot return to that before charging even the LIB is fully discharged, which indicates the process is irreversible. Moreover, the embedded of lithium also shows a charging current dependent behavior that slower charging rate has more significant effect on the lattice spacing increasing. The crystalline structure of the separator undergo different charging rate is firstly revealed by using *in-situ* XRD and the results can be used for improving and rationally designing separators which can broadly be applied in diverse conditions, such as low temperature.

# **Suppression of degradation of lithium ion batteries for $\text{LiFePO}_4\text{@C}$ batteries by nano Si surface modification**

Wenyu Yang, Xiang Chen, Mingzhong Zou, Guiying Zhao, Jiaxin Li, Yingbin Lin, Zhigao Huang\*

College of Physics and Energy, Fujian Normal University, Fujian Provincial Key Laboratory of Quantum Manipulation and New Energy Materials, Fuzhou, 350117, China

**Abstract:** Si nanoparticles are deposited uniformly on the  $\text{LiFePO}_4\text{@C}$  electrode by a spray technique. And the effect of Si incorporation on the electrochemical performances of  $\text{LiFePO}_4\text{@C}$  18650 cylindrical cells is investigated systematically by charge-discharge testing, cyclic voltammograms, AC impedance spectroscopy, respectively. At the same time, the aging and degradation of those cells have been studied. Non-destructive electrochemical methods were used to examine the capacity loss, voltage drop, resistance change, lithium loss, and active material loss during the life testing. The measuring results of the cycle life indicated that the capacity loss was strongly influenced by the rate, temperature, surface modification and discharge states (DOS). Especially, nano Si surface modification suppresses greatly the degradation of those cells. Moreover, the rate, temperature, time, and surface modification dependences of the cycle life were discussed.

# Processing and Characterization of $\text{Li}_4\text{Ti}_5\text{O}_{12}$ (LTO) Spinel Thin -Film for Li Battery Applications

Shu-Yi Tsai<sup>1</sup>, Chung-Ta Ni<sup>1</sup>, Kuan-Zong Fung<sup>1</sup>

<sup>1</sup>Research Center for Energy Technology and Strategy, Department of Materials Science and Engineering, National Cheng Kung University, No. 1, University Road, Tainan 70101, Taiwan, ROC  
*willxkimo@yahoo.com.tw*

Lithium titanium oxide spinel  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  has been reported to be a zero-strain lithium insertion host material because it exhibits extremely small variations of the lattice parameters during the charge and discharge processes. In general, Poor adhesion between thin-film electrode and substrates is the common cause for performance degradation of thin-film electrode during repeated charge/discharge tests. Thus,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  spinel may be the ideal candidate for the anode of thin-film Li ion battery for long cycle applications.

However, unmodified  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  usually exhibits poor rate performance, which mainly results from its low electronic conductivity (ca.  $10^{-13} \text{ S}\cdot\text{cm}^{-1}$ ) and moderate  $\text{Li}^+$  diffusion coefficient ( $10^{-8} \text{ cm}^2\cdot\text{s}^{-1}$ ). In addition, different electrochemical behaviors will be expected when  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  spinel is prepared in thin-film compared to that in power forms. Therefore, the objective of this work is (1) to enhance the conductivity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  spinel by substitution of aliovalent dopants for Ti ions, (2) to fabricate thin film of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  spinel by using RF-sputtering technique, (2) to investigate the effect of annealing temperature/atmospheres on the electrical/electrochemical properties of thin film  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ , (3) to evaluate the feasibility of using thin film of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  as anode for Li microbattery applications. In this study, the  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  thin film was deposited on either the Si substrate or glass substrate by sputtering technique. The crystallization of deposited  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  thin film will be enhanced by annealing at various atmospheres and temperatures. The single phase  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  was finally obtained after co- sputtering of Li-containing and Ti-containing targets. The crystal structure and crystallization will be examined by glancing XRD. The resistivity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  thin film will be evaluated by four probe technique and our novel micrometre measurement system. The capacity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  thin film will be evaluated from charge/discharge test

# Observation of Spinel Formation on Capacity Fading of Li-rich Layer-structured Cathode Materials

Chung-Ta Ni, Shu-Yi Tsai, Kuan-Zong Fung, Wei-Zhi Lin

*Department of Materials Science and Engineering, National Cheng Kung University*

*No.1 University Road, Tainan City, Taiwan 70101*

*chungtani@gmail.com*

Li rich layered composite cathode  $x\text{Li}_2\text{MnO}_3 \cdot (1-x)\text{LiMO}_2$  ( $M = \text{Mn, Ni, Co, etc.}$ ) materials have received much attention due to their high reversible capacity greater than 250mAh/g for Li-ion battery applications. There are few mechanisms have been proposed to explain their intercalation/deintercalation behavior based on the charge/discharge results. Although the initial capacity of Li-rich layer-structured cathode may reach as high as 250 mAh/g, a gradual capacity fading after cycling was observed. In Order to understand the causes for capacity fading of these  $x\text{Li}_2\text{MnO}_3 \cdot (1-x)\text{LiMO}_2$  materials, detailed structural analysis/characterization was performed.

In this work, the TEM structural analysis clearly shows that the formation of spinel phase after cycling. The layer structure to spinel phase transformation may be caused by the redox reaction of transition metal ions through charging/discharging tests. The reasons for capacity may be due to a large lattice distortion resulting in lattice breakdown accompanying repeated intercalation/deintercalation. Interestingly, the surface treatment of a spinel coating on the Li-rich layer-structured cathode tends to suppress the capacity fading compared to the uncoated ones.

Therefore, the effect of changing oxidation state of transition metal ions in the layered structures on the capacity fading was examined using XRD, SEM, TEM

# Island-like deposition of lithium manganese oxide spinel ( $\text{LiMn}_2\text{O}_4$ ) in all-solid-state thin film lithium ion battery

Tien-Hsiang Hsueh, Chi-Hung Su, Der-Jun Jan, Yuh-Jenq Yu, Yuan-Ruei Jheng

*Email address: Tien-Hsiang Hsueh*

Thin-film lithium-ion batteries (LiBs) are the most competitive low-power sources for various kinds of micro-electro-mechanical systems and have been extensively researched. In this paper, the battery was composed of thin film lithium metal anode, lithium phosphorus oxynitride (LiPON) solid electrolyte, and island-like deposition of lithium manganese oxide spinel ( $\text{LiMn}_2\text{O}_4$ ) cathode. LiPON and  $\text{LiMn}_2\text{O}_4$  were deposited by a radio frequency magnetron sputtering system, and lithium metal was deposited by thermal evaporation coater. Electrochemical characterization of this flexible lithium-ion battery shows a discharge capacity of  $110 \mu\text{Ah}$  between 4.3V and 3V at a current density of  $10 \mu\text{A}/\text{cm}^2$  (0.5C). The capacity retention was achieved 90% after 50 charge-discharge cycles between 4.3V and 3V at a current density of  $20 \mu\text{A}/\text{cm}^2$  (1C). Obviously, island-like deposition of thin film increased the charge exchange rate; this lithium-ion battery also exhibited a high C-rate performance, with better capacity retention of 61% at  $200 \mu\text{A}/\text{cm}^2$  (10C).

Figure L. SEM image of island-like deposition of  $\text{LiMn}_2\text{O}_4$  thin film.

Figure R. Scheme of the island-like deposition of  $\text{LiMn}_2\text{O}_4$  thin films in all-solid-state lithium ion battery.

Si nanoparticles have been promising materials for electronic devices, photovoltaics, lithium ion battery anode, optical and biological applications. To use active material as lithium ion battery anode we were synthesized by atmospheric microwave plasma pyrolysis method using  $\text{SiCl}_4$  as starting materials.  $\text{H}_2$  was the main parameter during the synthesis of Si nanoparticles as shown in the following reaction,  $\text{SiCl}_4 + 2\text{H}_2 \leftrightarrow \text{Si} + 4\text{HCl}$ .  $\text{H}_2$  flow rate effects on Si nanoparticles were investigated by using SEM, TEM, XRD, and XPS. Atmospheric microwave plasma pyrolysis system for synthesis of Si nanoparticles consisted of a power generator, feeder, reactor, trap and scrubber.  $\text{H}_2$  was injected through two nozzles in atmospheric microwave plasma pyrolysis system and referred to as swirling and reactive gas. From SEM, TEM, XRD, and XPS analysis,  $\text{H}_2$  flow rate and  $\text{H}_2$  injection method in plasma and reaction zone were critical to synthesize crystalline Si nanoparticles. Much more amount of  $\text{H}_2$  than the amount of  $\text{H}_2$  expected was required to synthesize crystalline Si nanoparticles from  $\text{SiCl}_4$ . The  $\text{H}_2$  as swirling gas was more important than  $\text{H}_2$  as reactive gas because of  $\text{H}_2$  flow rate. The synthesized Si nanoparticles had core-shell structures covered with amorphous  $\text{SiO}_x$  shell.

# Tuning the Electronic Structure of Layered Oxides Electrodes for Reversible Anionic Redox in Lithium Ion Batteries

Biao Li, Huijun Yan, Li An, Hang Wei, Jin Ma, Dingguo Xia\*

*Beijing Key Lab of Theory and Technology for Advanced Batteries Materials, College of Engineering, Peking University, Beijing 100871, P. R. China. Email: [dgxia@pku.edu.cn](mailto:dgxia@pku.edu.cn)*

Lithium ion batteries have been increasingly urged with high energy density and long cycle life to meet the increasing requirements for portable electronics, use of renewable energy and electric vehicles. The availability of the appropriate cathode material is crucial for the development of lithium ion batteries.  $\text{Li}_{1+x}\text{Ni}_y\text{Co}_z\text{Mn}_{1-x-y-z}\text{O}_2$  can deliver a high capacity of more than  $250 \text{ mA h g}^{-1}$ , provoking world wide attentions for lithium rich layered oxides, such as  $\text{Li}_2\text{Ru}_{1-y}\text{M}_y\text{O}_3$  ( $\text{M}=\text{Mn}$ ,  $\text{Sn}$ , and  $\text{Ti}$ ) and  $\text{Li}_{1.211}\text{Mo}_{0.467}\text{Cr}_{0.3}\text{O}_2$ . A common feature accounting for the high capacities of these lithium rich materials is supposed to be the two redox processes involving both of cation and anion<sup>[1]</sup>. However, the stability of these high capacity electrodes is limited for long cycle life due to its structural unstability, which is supposed to be caused by the excessive participation of the anionic redox<sup>[2]</sup>. Here, in this work, we expect to develop a strategy by tuning the electronic structure of the layered oxides to realize the reversibility of the anionic redox. It is shown by DFT calculation method that the reversible anionic redox can be obtained within a certain extent of participation in redox reaction of the anionic ions. We chose interstitial site doping in the layered oxides of  $\text{Li}_2\text{RuO}_3$  to tune its electronic structure. The resulted materials show decreased covalency and lowered O 2p band. The charge/discharge behavior has significant change for the first cycle and subsequent cycles.

This work was financially supported by the National High Technology Research and Development Program (2012AA052201, 2012AA110102), the National Natural Science Foundation of China (11179001).

### Abstract

The reaction mechanisms of Li-ion batteries materials are broadly classified in to intercalation/de-intercalation, alloying-de-alloying, conversion reaction and alloying and conversion reaction. Binary oxides like  $\text{MO}_2$  (M= Mn, Ru, Ti, Mo) undergoes intercalation reaction with Li. In order to understand the effect of matrix element and crystal structure, we studied the comparative electrochemical studies of  $\text{MO}_2$ . The discharge -charge profiles and capacity values of various binary metal oxides  $\text{MO}_2$  (M= Ti, Mn, Mo, Ru) are shown in Fig. 1. Samples were prepared by various chemical methods. Preliminary electrochemical studies show a reversible capacity (1<sup>st</sup> charge) are 150, 160, 140 and 280 mAh/g respectively for  $\text{TiO}_2$ ,  $\text{MoO}_2$ ,  $\text{MnO}_2$ , and  $\text{RuO}_2$  at a current rate of 33 mA/g at room temperature. The discharge-charge profiles show a differences in the discharge-charge voltage profiles was noted with different matrix elements. The charge voltage of the order of  $\text{MnO}_2 > \text{RuO}_2 > \text{TiO}_2 > \text{MoO}_2$ . Two stages of voltage plateaux was noted with  $\text{MoO}_2$  compounds. Ex-situ XRD studies on selected voltages were discussed in detail and also preliminary electrochemical studies with Li-air battery studies were presented on select materials.

# Composite positive electrode using sulfur/micro porous carbon for high-performance lithium-sulfur battery

Yukiko Matsui, Takuya Takahashi, Satoshi Uchida, Masaki Yamagata, and Masashi Ishikawa  
Department of Chemistry and Materials Engineering, Faculty of Chemistry, Materials and  
Bioengineering, Kansai University  
3-3-35 Yamate-cho, Suita 564-8680, Japan  
e-mail address: yamagata@kansai-u.ac.jp

Recent growth and demand for portable electronics and large-scale applications, such as electric vehicles and renewable energy storage devices, require advanced lithium-ion batteries that have high power and high storage capacity. These ideal characteristics can be achieved by improving charge-discharge performance of positive electrodes, and rightly, many efforts have been done to develop cathode active materials. Lithium sulphide ( $\text{Li}_2\text{S}$ ) is one of a promising cathode material for high-energy lithium batteries, because of its extremely high theoretical capacity of  $1672 \text{ mAh g}^{-1}$ . However, it is difficult to realize high-performance of lithium-sulfur battery due to some crucial problems, especially low electric conductivity of sulfur and dissolution of polysulfides formed during charge-discharge operation. Herein, we prepared and investigated a highly stable sulfur positive electrode using micro-porous carbon in several non-aqueous electrolytes including solvate ionic liquid electrolyte [1] to constructing high-performance lithium-sulfur battery.

Figure 1 shows charge-discharge cyclability of a composite electrode based on micro-porous carbon containing sulfur (a S/C electrode) in several non-aqueous electrolytes; solvate ionic liquid electrolyte composed of LiTFSI, tetraethylene glycol dimethyl ether (tetraglyme, G4) and hydro fluoro ether (HFE)[1],  $1.0 \text{ mol dm}^{-3}$  LiFSI/EMImFSI ( $\text{FSI}^- = \text{bis}(\text{fluorosulfonyl})\text{imide}$ ;  $\text{EMIm}^+ = 1\text{-ethyl-3-methylimidazolium}$ ), and a conventional organic-solvent-based electrolyte ( $1.0 \text{ mol dm}^{-3}$   $\text{LiPF}_6/\text{EC}+\text{DMC}$ ) at charge-discharge rate of 0.1/0.07 C-rate in a cell voltage range from 1.0 V (or 1.2 V for LiFSI/EMImFSI) to 3.0 V. Stable charge-discharge operations of the S/C electrode with ca.  $1100 \text{ mAh g}^{-1}$  at a  $100^{\text{th}}$  cycle are observed regardless of the kinds of the electrolytes, suggesting that using micro-porous carbon might provide high retainability of polysulfides. Figure 2 compares the discharge capacity of the S/C composite electrode in three solvate ionic liquid-based electrolyte; LiFSI/G4, LiFSI/G4+HFE, and LiTFSI/G4+HFE as well as  $\text{LiPF}_6/\text{EC}+\text{DMC}$  at a discharge C-rate from 0.1 to 2.0 C-rate. An apparent contrast in discharge capability is observed more than 1.0 C-rate. Among the cells with four electrolytes, the remarkably high rate capability is achieved for the cell with the LiFSI/G4+HFE system; its discharge capacity exhibits ca.  $1200 \text{ mAh g}^{-1}$  at 2.0 C-rate.

In the present study, we also constructed a Si/S cell to evaluate its practical usability. According to charge-discharge measurements, the Si/S cell shows highly stable cycling behavior with high discharge capacity over  $900 \text{ mAh g}^{-1}$  for 300 cycles

The lithium-ion battery (LIB) is a preferred power source for hybrid electric vehicle (HEV) applications due to its outstanding characteristics such as high energy density, modular scalability, long cycle life, and low self-discharge rate among others. In a battery module for HEV applications, an uneven temperature distribution in the module can be created depending on the operating conditions and the types of thermal management. Uneven temperature distribution in a module could cause an electrical imbalance and thus lead to the lower performance and shorter life of battery. It is, therefore, important to calculate accurately the uneven temperature distribution in a battery module in order to achieve the optimum performance and long life of the battery module.

In this work, a modeling is performed to investigate the effect of the operating condition on the thermal behavior of an LIB module. The thermal conductivities of the various compartments of a battery cell are estimated based on the equivalent network of parallel/series thermal resistances of the battery components. The heat generation rate in an LIB cell is calculated by using the modeling results of the potential and current density distribution of a battery cell. The temperature distributions in the LIB module obtained from the modeling are in good agreement with the experimental measurement.

The battery module consisting of 8 prismatic pouch-type LIB cells modeled in this work is shown in Fig. 1. In Fig. 2, the temperature distributions of the LIB cells within the module at a few cross sections along the y direction are shown at the discharge time of 960 s with the discharge rate of 3C for natural convection cooling. The temperatures of the two cells located at the bottom and top of the module are lower than those of the other cells.

Fig. 1. Finite volume mesh used for CFD calculations and the direction of cooling air flow.

Recent research and development advancements of lithium power sources has shown that composite polymer electrolytes have gained a significant attention. Composite polymer electrolytes are difficult organized heterogeneous materials, so it seems to be practically impossible to create a highly conductive electrolyte using random selection of raw materials and manufacturing method. Thereby, it is especially important to determine the mechanism of charge transport through the CPE.

The composite based on PVDF, with the incorporation of an inorganic filler -  $\text{TiO}_2$  and  $\text{LiClO}_4$ , as the dopant salt was selected in this study. The effect of changes in physical and chemical properties, shape, quantity and methods of the filler particles incorporation in the polymer membrane were observed.

Results of the experiment showed that small concentrations (1-5%) of the filler contribute to increase the ionic conductivity, but further additive (10-50%) triggers the opposite mechanism. The shape of the particles and their distribution influenced on the stability of electrode-electrolyte interface. Analysis of all the variations is optimal point correlation of mechanical properties and high ionic conductivity.

The mechanism of charge transfer based on the acid-base interaction between the filler particles and the lithium cation was proposed. This illustrates competitive character of introduced components leads to a change in the kinetics of the processes occurring at the electrode-electrolyte interface. It is believed that the introduction of neutral filler, facilitates the formation of polymer dative bands that leads to a decrease in its bonding strength between the cation of lithium and polymer chains, which increases the ion migration.

Electromobility undergoes a rapid development in the world nowadays. The problem of current electric vehicles (EV) is the lack of battery capacity which limits their potential range. The solution of this problem could be Li-S batteries with their theoretical capacity of 1675 mAh/g and specific energy of ~ 3200 Wh/kg which greatly exceeds the possibilities of current commercial batteries. Before releasing these batteries into practice, it is necessary to solve a number of problems, such as a very complicated conversion of sulphur to Li<sub>2</sub>S and back again without settling soluble polysulfide at the anode during cycling, which leads to a decrease of capacity. Another problem is the expansion of sulphur during cycling, when, during the conversion of sulphur to Li<sub>2</sub>S, the volume expansion of about 80% occurs. This expansion leads to a big stress to the cathode and decreases its capacity. A possible solution of both these problems is the correct choice of carbon which encapsulates sulphur and a binder which can respond to the changes of volume without the loss of contact between particles of the electrode. This paper deals with the influence of used carbon and binder to the electrochemical properties of Li-S batteries. Standard Super P carbon and mesoporous carbon in combination with binders PVDF, PEO and PVP were used for testing. It was found that there was an increase of the capacity and stability of the electrode during cycling at various C-Rates. A stable and reversible capacity of about 600 mAh/g was achieved during cycling at 0.2 C and almost 400 mAh/g during cycling at 0.5 C.

The lithium-sulfur battery is a promising rechargeable lithium-ion battery system that has a high theoretical capacity of 1675 (mAh/g) and high theoretical energy density (2500 Wh/kg). However, it suffers several drawbacks such as poor conductivity and huge volume change of active materials, dissolution of intermediates, safety issue of lithium metals, etc. which prevent it to be commercialized. In this study, synthesized carbon materials with various defects and functional groups were introduced to prepare sulfur/carbon composites and investigate the interactions between carbon defects and sulfur or polysulfides. Further characterization and electrochemical measurements were conducted to establish the relationship between the interactions and electrochemical performance of sulfur/carbon composite materials.

# Electrochemical Intercalation of Anions into Graphite – The Role of Anion Structure and Solvent Properties

Kolja Beltrop<sup>\*</sup>, Paul Meister, Olga Fromm, Martin Winter, Tobias Placke

University of Münster, MEET Battery Research Center, Institute of Physical Chemistry Corrensstr. 46,

<sup>\*</sup>[kolja.beltrop@uni-muenster.de](mailto:kolja.beltrop@uni-muenster.de)

The increasing demand for large scale energy storage capabilities causes a big field of research to make the battery systems safer and environmentally benign. A promising approach is the replacement of conventional volatile and highly flammable organic solvent-based electrolytes by ionic liquids (ILs) as the main component of the electrolyte. ILs exhibit excellent properties such as a broad electrochemical stability window, a high thermal stability, non-flammability and a high ionic conductivity.[1] A further prevention of pollution is the application of carbon-based, transition metal-free electrode materials. Recently, “dual-ion” and “dual-graphite” cells were introduced which are composed of a lithium-incorporating anode and an anion incorporating graphite-based cathode.[2][3] During charge the ions intercalate into the electrode active materials and are released back into the electrolyte during discharge (see Figure 1). Since the cathode potential reaches and may even exceed 5 V vs.  $\text{Li}/\text{Li}^+$ , electrolytes that exhibit a high stability vs. oxidation are necessary. For that reason, ILs with their versatile properties were introduced and investigated. The state of the art electrolyte for this system is composed of a solution of lithium bis(trifluoromethanesulfonyl) imide ( $\text{LiTFSI}$ ) in *N*-butyl-*N*-methylpyrrolidinium bis(trifluoromethanesulfonyl) imide ( $\text{Pyr}_{14}\text{TFSI}$ ). In order to increase the specific capacity of this system, one main strategy is to focus on the intercalation of smaller anions than TFSI into the graphite structure. In this context, the major challenge is the synthesis of ILs or mixtures of ILs with organic electrolytes consisting of small anions to provide an electrochemically stable electrolyte. Interestingly, not only the size and shape of the intercalated anions plays a major role in view of onset potential for anion uptake as well as discharge capacity. Instead, also more complex coherences such as ion association, self-aggregation of ions as well as solvent co-intercalation have to be taken into consideration. In this work, we investigate the electrochemical intercalation of anions with different shapes and sizes from either IL or organic based electrolytes into a graphite-based cathode. Against this background, the influence of side chain modifications within the anion structure on the intercalation behavior was studied using different electrochemical analysis techniques. Therefore, in this contribution we will give new insights to the question if the anion size is the main issue to tailor the reversible capacity for anion intercalation.

Ni-based layer structured cathode materials have been considered as one of the most promising candidates for next generation batteries due to their higher energy density, less toxicity, and lower cost compared with those of  $\text{LiCoO}_2$ . Each of transition metal inside layered lithium transition metal oxides acts to relieve the charge imbalance that occurs during either the insertion or removal of lithium from the structure during the reduction or oxidation process, and thus their incorporation strongly affects the overall electrochemical performance. For example, the incorporation of Ni increases the overall capacity of the cathode; however, Ni-rich cathodes have also been associated with significant safety issues. Here, we take advantage of electron microscopy to directly investigate the evolution of the surface structure of  $\text{Li}_x\text{Ni}_y\text{Mn}_z\text{Co}_{1-y-z}\text{O}_2$  cathode materials with y and z of 0.8 and 0.1, 0.6 and 0.2, 0.4 and 0.3 (referred to as NMC811, NMC622, NMC433, respectively) that have been cycled under various cutoff voltage conditions. Bright field (BF) images, selected area electron diffraction (SAED) patterns, and electron energy loss (EEL) spectra from the oxygen K-edge and transition metal (TM: nickel, manganese, cobalt) L-edges of charged NMC cathode materials are recorded from individual particles as a function of charge cut-off voltages. Statistical analysis for several particles is also performed in order to examine particle-to-particle variation, which becomes significant in NMC having a high Ni content. This study demonstrates that the transition metal content has a strong impact on both the electrochemical properties and the structural stability of charged NMC materials, and the structural degradation is critically affected by the cutoff voltage. For better understanding of degradation mechanism under high cut-off voltage operation, the relation between impedance change and the degree of cycle degradation will be also discussed. All the details will be available at the meeting.

# Detailed “Mapping” of Internal Resistance in Li-S Batteries

Matthew J. Lacey, Kristina Edström, Daniel Brandell  
Department of Chemistry – Ångström Laboratory, Uppsala University  
Box 538, Lägerhyddsvägen 1, SE-751 21 Uppsala, SWEDEN  
matthew.lacey@kemi.uu.se

Measurement of internal resistance is an important indicator of state-of-health and stability in batteries. This is frequently accomplished with the use of electrochemical impedance spectroscopy (EIS), which is a powerful technique enabling the probing of a range of processes across a wide timescale, but one which requires specialist equipment and can very often be difficult to interpret correctly. Furthermore, it can be a complex task to incorporate impedance measurements into standard battery testing procedures such as galvanostatic cycling.

In this work we describe a relatively simple experiment for visualising the change in internal resistance in a battery during galvanostatic cycling based on the current-interrupt method. Repeated short interruptions in the current, for example, every few minutes for a fraction of a second, can be easily analysed by a simple computer program and presented as a ‘heat map’ to visualise the changes in internal resistance over the full state-of-charge range and over many cycles.

This technique has been applied here to the study of the Li-S cell, which, due to its unique electrochemistry, shows significant changes in resistance during charge and discharge, asymmetry between the charge and discharge processes and often unpredictable changes over a large number of cycles, even if the capacity is relatively stable. The timescale of the measurement may also be varied allowing, in principle, the separation of ionic/electronic resistances from, for example, charge transfer. The use of this technique for the comparison of different electrode materials will also be presented.

Figure: internal resistance “map” of a Li-S cell cycled galvanostatically at a constant rate of  $C/10$ . The plot above comprises 9,727 unique measurements. Resistance,  $R$  was determined by measuring  $dE/dI$  over a 0.5 s current interruption every five minutes.

# Nanostructured ZnFe<sub>2</sub>O<sub>4</sub>-based anodes for lithium-ion batteries – Novel synthesis route and analytical study on metal dissolution

Tobias Placke, Haiping Jia, Britta Vortmann, Martin Winter

*University of Münster, MEET Battery Research Center, Institute of Physical Chemistry, Corrensstr. 46,  
48149 Münster, Germany*

*\*tobiasplacke@uni-muenster.de*

The ever-growing demand for next-generation lithium-ion batteries (LIBs) with high specific energy/energy density as well as high power performance has prompted widespread research to develop novel electrode materials for both the anode and cathode.[1] There are mainly three types of anode materials for LIBs according to the different lithiation storage mechanisms: (1) intercalation materials such as graphite and insertion materials such as Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> spinel oxides or TiO<sub>2</sub> anatase; (2) lithium alloying materials, such as Si or Sn and (3) conversion materials, such as transition metal oxides like Fe<sub>3</sub>O<sub>4</sub> and MnO which store charge via a conversion reaction ( $\text{MO}_x + 2x\text{Li} \rightleftharpoons \text{M} + x\text{Li}_2\text{O}$ ). Among the latter ones, the nanostructured metal oxides, such as tin oxide and cobalt oxide have been extensively studied as alternative anode materials for use in LIBs over the past few years because of their large number of possibilities and their high specific capacity.[2, 3] Fe<sub>3</sub>O<sub>4</sub>, for example, gives a theoretical capacity of 926 mAh g<sup>-1</sup>, considering the completely reversible formation of four Li<sub>2</sub>O per formula unit.[3] The theoretical capacity of these transition metal oxides can be further increased by replacing one iron atom by an element which can reversibly form an alloy with lithium, such as zinc. This would result in an enhanced theoretical capacity of ca. 1000 mAh g<sup>-1</sup>, according to the reversible reaction involving nine lithium ions per formula unit of ZnFe<sub>2</sub>O<sub>4</sub>. [4] Considerable efforts have been devoted for the synthesis of ZnFe<sub>2</sub>O<sub>4</sub> with a variety of nanostructures, such as hollow spheres, octahedrons, nanofibers and nanorods.[5, 6] However, these morphologies were fabricated by synthetic or high temperature methods such as thermal decomposition, sol-gel or electrospinning technique. Among these methods, the sol-gel process has been considered to be a facile and effective way for designing novel nanomaterials with attractive properties. This is due to its simplicity, low cost of the raw material and equipment, possible large-scale production and most important advantage that the obtained material mostly present crystalline phase. In this work, we report a facile synthesis route, i.e. an ionic liquid-assisted sol-gel synthesis method, for the preparation of ZnFe<sub>2</sub>O<sub>4</sub>. The obtained material demonstrates a uniform morphology with fine particles which are composed of 50 nm-sized ZnFe<sub>2</sub>O<sub>4</sub> crystallites. Sucrose is employed as carbon source to coat the ZnFe<sub>2</sub>O<sub>4</sub> with a thin layer so as to enhance the surface electronic conductivity as well as the surface area for use as high-capacity and high-power anode material. Furthermore, analytical studies are carried out to identify the possibility of metal dissolution during electrochemical cycling at different operating conditions as well as the influence on the overall material stability.

# Buffer Effects of Electrolyte Additives on Lead-Acid Flow Batteries

Hsun-Yi Chen, Chih-Wei Chang, and Dong-Yi Chao

National Taiwan University, Dept. of Bio-Industrial Mechatronics Engineering

No. 1, Sec. 4, Roosevelt Rd., Taipei, 10617, Taiwan

hsunyichen@ntu.edu.tw

A single-flow, membrane-less lead acid redox flow battery (RFB), which is comprised of inexpensive components and materials, is promising for stationary energy storage. However, the lead-acid RFB currently has limited cycle life and low energy efficiency when operated at high C-rate, and is not ready for power grid applications.

One crucial factor that is identified to be responsible for degradation of lead-acid RFBs is the formation of passivation layers on electrodes when acidity of the electrolyte fluctuates appreciably. Although the growth mechanism is not fully understood, it is believed that a low conductive film of  $Pb_3O_4$  can form at the positive electrodes when the pH value of the electrolyte is relatively low. As shown in Fig. 1, deep charge/discharge cycles of a lead-acid RFB can induce significant electrolyte pH changes, and ultimately leads to a trend towards lower pH values. Accumulation of the passivation layer at electrodes during charge/discharge cycles then, in turn, leads to poor battery efficiency and higher proton concentration in the electrolyte in the long run.

In order to alleviate changes of proton concentration, pH buffering agents such as potassium acetate or sodium borate can be added to the electrolyte. This study focuses on investigating the buffer effects of various electrolyte additives on lead-acid RFBs. The quality of electroplated Pb and  $PbO_2$  with and without buffering additives is compared through impedance measurements and optical micrographs. Cyclic voltammetry will be performed for different electrolyte systems before conducting long term charge/discharge cycling experiments. We aim to identify the effective kind and the appropriate amount of additives for lead-acid RFBs to prolong their cycle life.

Fig. 1. Black line represents cell potential vs. time response for 10 charge/discharge cycle at current density of  $15 \text{ mAcm}^{-2}$ . Blue dashed line indicates pH values of the methanesulfonat based electrolyte.

# Probing the Oxygen Evolution Efficiency of Redox Mediator-Catalyzed Lithium-Oxygen Batteries using On-Line Electrochemical Mass Spectrometer

Zhuojian Liang, Yi-Chun Lu\*

Department of Mechanical and Automation Engineering, Shun Hing Institute of Advanced Engineering,  
The Chinese University of Hong Kong, Shatin, N.T., Hong Kong SAR, China

\*yichunlu@mae.cuhk.edu.hk

High charge overpotential is a major challenge in achieving efficient Li-O<sub>2</sub> batteries with long cycle life.<sup>1</sup> Redox mediators have been reported effective in reducing the overpotential during charge of Li-O<sub>2</sub> batteries.<sup>2-6</sup> However, limited evidence is available on how redox mediators influence the gas evolution efficiency upon charging.

In this study, we exploit quantitative on-line electrochemical mass spectrometer (OEMS)<sup>7,8</sup> to analyze the gas evolved during charge with and without redox mediator. Among many reported redox mediators, lithium iodide (LiI)<sup>2,3</sup> is one of the most effective and widely used redox mediators for rechargeable Li-O<sub>2</sub> batteries. Figure 1 shows the first galvanostatic charging voltage profile of a pre-discharged Vulcan carbon electrode and the corresponding evolution rate of O<sub>2</sub> and CO<sub>2</sub> measured during charge by the OEMS. The reduced overpotential for the cell with 10mM LiI agrees with a previous studies.<sup>2,3</sup> In both cells, a high evolution rate of O<sub>2</sub> was observed throughout the charge, indicating the domination of reversible Li<sub>2</sub>O<sub>2</sub> oxidation in the charge process with and without LiI. The OER/ORR ratio, which characterizes the degree of O<sub>2</sub> recovery efficiency and the rechargeability, is 0.860 and 0.868 for cells with and without LiI, respectively. The deviation of the ratio from 1.000 suggests that parasitic reactions still exists when the cell is charged with LiI. In addition, the similar ratios imply that the O<sub>2</sub> efficiency is not affected by LiI. In both cells, the oxygen evolution reaction (OER) is followed by CO<sub>2</sub> evolution, which is widely observed to be generated from decomposition of carbon cathode, electrolyte or parasitic products (e.g. carbonate)<sup>8</sup>. The charge voltage of the cell without LiI increases faster than the cell with LiI. The former exhibits a voltage peak during charge, which is accompanied by a dip in the O<sub>2</sub> gas evolution profile. Such features were not observed in the cell with 10mM LiI, suggesting different charging mechanisms with and without LiI, which leads to difference in gas evolution patterns. Our study provides direct quantitative evidence on the efficacy of catalytic effect and gas evolution of redox mediators for Li-O<sub>2</sub> batteries. Further investigation on the parasitic products and the long term catalytic effect of the reported redox mediators (e.g. LiI,<sup>2,3</sup> 2,2,6,6-Tetramethylpiperidin-1-yl)oxyl (TEMPO),<sup>4</sup> iron phthalocyanine (FePc)<sup>6</sup>) will be discussed.

Fig. 1. First galvanostatic charging voltage and gas evolution profile of Li-O<sub>2</sub> cells with and without 10mM LiI in 1M LiTFSI diglyme. The cells were discharged at 500mA/g to 500mAh/g prior to charge. The spike in the 10mM LiI OER profile is caused by the accumulation and sudden release of a gas bubble in the cell, which do not affect the overall OER quantification.

## **Study of the kinetic of LiFePO<sub>4</sub> oxidation in aqueous solutions**

Malchik F., Kurbatov A.

*al-Farabi Kazakh National university*

*71 al- Farabi Ave., Almaty, Republic of Kazakhstan*

[Frodo-007@mail.ru](mailto:Frodo-007@mail.ru)

Based on the analysis of chemical oxidation of LiFePO<sub>4</sub> cathode material in aqueous solutions we attempted to identify the mechanism of lithium deintercalation in oxidation.

It was shown that the reaction rate depends on the concentration of the oxidant and the pH. At low concentrations of oxidizing agent in alkaline media limiting step is the delivery of oxidant to the surface of the particles. After reaching a certain concentration of oxidant, the reaction rate becomes constant, which may be due to a change in the limiting stage - the reaction on the surface. In the range of pH 7-10, the impact the basic solution to the oxidation rate is negligible. Although outside of this area, we can observe a significant increase in the rate of reaction in acidic media and the slowdown in alkaline media. In acidic media is possible to achieve complete oxidation of the material in a short time (300-600 s), allowing to quickly determine the degree of oxidation of Fe in the compound.

Rechargeable Li-ions batteries are still the frontrunners for powering portable electronic devices and for use in electric vehicles<sup>1</sup>. Improving the safety and energy density of the Li-ions batteries is the focus of current research. Besides improving the materials characteristics used in the Li-batteries and thus the overall battery performance, an alternative pathway consists in replacement of lithium by other elements, for example magnesium. Rechargeable Mg batteries have been already recognized as a promising technology for energy storage and conversion and lot of work has already been done on their development<sup>2</sup>. Furthermore,  $\text{V}_2\text{O}_5$  has been studied as a positive electrode material showing good performance not just for  $\text{Li}^+$  but also for  $\text{Mg}^{2+}$  ions insertion<sup>3</sup>. However, the energy and power density of current Mg ion batteries is much lower than for Li ion batteries.

In this study several synthetic routes such as sonochemical modification of commercial  $\text{V}_2\text{O}_5$  powder, anodization of V metal, electrochemical deposition and hydrothermal synthesis have been used to obtain  $\text{V}_2\text{O}_5$ . Scanning electron microscopy revealed different morphologies, varying from nanofibers obtained by the sonochemical treatment and electrochemical deposition, nanotubes obtained by the anodization method and hollow nanospheres of  $\text{V}_2\text{O}_5$  obtained by the hydrothermal synthesis (cf. Figure 1). The interaction of the prepared materials with the  $\text{Mg}^{2+}$  ions using different electrolytes has been studied via electrochemical techniques such as slow scan cyclic voltammetry (SSCV), potentiostatic intermittent titration technique (PITT) and electrochemical impedance spectroscopy (EIS), in order to understand the mechanism of the intercalation process and to analyze the influence of the morphology on the kinetics<sup>4</sup>.

**Figure 1.** SEM images of (a) hollow  $\text{V}_2\text{O}_5$ -nanospheres, (b) electrodeposited  $\text{V}_2\text{O}_5$  and (c) ultrasonicated  $\text{V}_2\text{O}_5$

## 1. INTRODUCTION

Lithium ion batteries have attracted attention as a possible methodology for solving current environmental and energy problems. However, a greater power density and cycle life are required to satisfy industrial needs.  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  is as an alternative anode material to graphite due to its long cycle life and good high-rate performance. Unfortunately,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  has poor electronic conductivity (ca.  $10^{-13} \text{ S cm}^{-1}$ ) [1]. We have used a new carbon material called “Marimo carbon” as a conductivity assistant in order to improve the overall electric conductivity. Marimo carbon has a spherical structure that consists of an oxidized diamond as its core and radial carbon nanofilaments (CNFs) [2]. The electrolytes can easily sink into the vacant spaces of the CNFs, consequently, the improved electric conductivity is expected to obtain with the  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ /Marimo carbon composite. Although acetylene black is widely used as a conductivity assistant, the material can easily aggregate to give a non-uniform distribution. Conversely, it is expected that Marimo carbon will provide a better accessibility by allowing the  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  particles to fit in between the vacant spaces of the CNFs.

## 2. EXPERIMENTS

Ni/Oxidized diamond were used as a catalyst for the synthesis of the catalyst, Marimo carbon. Marimo carbon was grown by heating the catalyst at 550 °C for 3 h in methane gas as the reactant. Marimo carbon was then added to a 0.4 M LiOH solution and dispersed with an ultrasonic generator. (Marimo carbon was not added to a preparation of pure  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ .) Hydrogen peroxide and titanium tetraisopropoxide were then added, and the solution was stirred for 1 h. The solution was transferred into a Teflon-lined stainless steel autoclave, which was then heated at 130 °C for 12 h. After cooling to room temperature, the solid product was obtained by centrifugation and washed with distilled water. The sample was then dried in vacuo and calcined at 400 °C for 6 h in argon. Electrochemical measurements for the composite were performed using CR2032 type cells. In the preparation of the working electrodes, a mixture of either a  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ /Marimo carbon composite or pure  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  was pasted on Cu foil with polyvinylidene fluoride (9:1 wt.%). Lithium foil was used as a counter electrode, and a solution of 1 M  $\text{LiPF}_6$  in ethylene carbonate and diethyl carbonate (EC + DEC = 1:1 vol.%) were used as an electrolyte.

## 3. RESULTS AND DISCUSSION

Figure 1 shows the rate performances of all samples with discharge rates ranging from 1 to 20 C. The discharge capacity decreases with an increasing discharge rate. In particular, pure  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  shows the greatest amount of decay as a function of an increasing discharge rate. This indicates that pure  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  has poor electrical conductivity because it lacks a conductive path. In comparison, the decay of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  with Marimo carbon composite is smaller. This is particularly observed in the discharge capacity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ /50 wt.% Marimo carbon, which has a value of  $128.5 \text{ mAh g}^{-1}$  (Pure  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  is only  $43.8 \text{ mAh g}^{-1}$ ) at 10 C. This is 73.4 % (Pure  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  is only 25 %) of the theoretical capacity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  ( $175 \text{ mAh g}^{-1}$ ), which suggests that the electrical conductivity was improved by the conductive path of Marimo carbon. These results show that Marimo carbon did indeed function as a conductivity assistant.

Li<sup>+</sup>-ion batteries (LIBs) are the state of the art energy storage technology in the transport sector and for portable electronic devices[1]. With respect to large scale applications, for instance as electricity buffer in combination with renewable energy sources, such as solar and wind power, LIBs suffer from high costs, mainly caused by the high Li-metal price, and limited resources[2]. While Li has a price of more than 4\$US per kg, the price of 1kg Na is much less 0.5\$US[3], and it is evenly distributed throughout the world, making it hence a promising Li-substitute.

Similar to the case of LIB anodes, it would be desirable to also use graphitic anodes for Na<sup>+</sup>-ion batteries, not only due to their ease in handling and their low costs, but also, because at least for Li ions the metal ion intercalation is highly reversible. For Na<sup>+</sup>-ions however, theoretical first-principal calculations predicted that no binary Na-graphite-intercalation-compounds (Na-GIC) can form due to an energetic instability[4]. Nevertheless, it was experimentally shown that Na<sup>+</sup>-ions can very well intercalate into graphite in the presence of an appropriate solvation shell, which leads to the formation of ternary Na-GICs[5].

In the present study, a range of electrolytes composed of sodium-salts, such as NaClO<sub>4</sub>, NaPF<sub>6</sub> and NaOTf, in combination with a variety of carbonate- (ethylene carbonate (EC), dimethyl carbonate (DMC), propylene carbonate (PC)) and ether-based solvents (mono-, di-, tri- and tetraglyme) is tested in view of their ability to form ternary Na-GICs. Electrochemical tests are the starting point, being complemented by application of in-situ methods, like Electrochemical Scanning Tunneling Microscopy (EC-STM) (Figure 1), the Electrochemical Quartz Crystal Microbalance technique (EQCM) and Electrochemical Impedance Spectroscopy (EIS).

Research on sodium-ion battery materials has recently boosted within the scientific community, as sodium resources are “unlimited”, low cost, and geographically distributed. [1,2] As graphite does unfortunately not significantly insert sodium ions [3], hard carbon (HC hereafter) is today the only practical negative electrode active material. Its main drawback is the high irreversible capacity upon the first cycle, well known also in Li-ion cells, which has important implications for cell balancing. This phenomenon is commonly related to surface reactivity and thus we have attempted to reduce it through coating. We developed a simple physical method, enabling conformal uniform particle coating [4,5] decreasing the surface area and allowing significant improvement in terms of the first cycle coulombic efficiency. [6]

After mitigation of the first cycle irreversible capacity loss, we became interested on the thermal dependence of HC electrochemical performance. The impressive thermal stability window of electrolytes based on a mixture of ethylene carbonate (EC) and propylene carbonate (PC) (vitreous transition for temperatures near -95°C and a single exothermic peak around 250°C in the DSC curves) [7] prompted us to undertake a systematic study on the electrochemical performances of HC electrodes tested at various temperatures ranging from -15°C up to 75°C. The performances of carbon coated HC cycled at 25°C and 75°C were evaluated at various C rates. A significantly higher reversible capacity is recorded upon cycling at 75°C (ca. 450 mAh/g at C/10) than at 25°C (ca. 325 mAh/g at C/10) with similar coulombic efficiencies (higher than 99% after 5 cycles). The reversible capacities recorded upon cycling at 0°C (ca. 260 mAh/g) and -15°C (ca. 265 mAh/g) at C/10 are very similar to the one achieved at 25°C and in all cases the coulombic efficiency was found to be higher than 99%. [6]

Electrochemical performances of HC at various temperatures pointed at the IR drop of the cell being determinant for achieving the highest reversible capacity (450 mAh/g at C/10, 75°C) and rate capability (340 mAh/g at 2C, 75°C) ever reported. Overall such results are encouraging in terms of high and low temperature Na-ion batteries operation which is highly important for application.

Li-O<sub>2</sub> battery works based on the reversible formation and decomposition of Li<sub>2</sub>O<sub>2</sub>, which is insulating and highly reactive. Designing catalytic cathode capable of controlling the Li<sub>2</sub>O<sub>2</sub> growth recently becomes a challenge to overcome this barrier. In this work, we gave a new design of catalytic cathode by growing porous honeycomb-like Au/ $\delta$ -MnO<sub>2</sub> electrocatalyst directly on conductive substrate. We found that Au/ $\delta$ -MnO<sub>2</sub> can catalyze the directed growth of Li<sub>2</sub>O<sub>2</sub> into thin/small form, only inside  $\delta$ -MnO<sub>2</sub> honeycombs, and along the surface of  $\delta$ -MnO<sub>2</sub> sheets. We proposed the catalytic mechanism of Au/ $\delta$ -MnO<sub>2</sub>, where Au plays a critical role in catalyzing the nucleation, crystallization and conformal growth of Li<sub>2</sub>O<sub>2</sub> on  $\delta$ -MnO<sub>2</sub> sheets. Li-O<sub>2</sub> batteries with Au/ $\delta$ -MnO<sub>2</sub> catalytic cathode show excellent electrochemical performance due to this favorable Li<sub>2</sub>O<sub>2</sub> growth habit. The battery yields a high capacity of 10600 mAh g<sup>-1</sup> with a low polarization of 0.91 V at 100 mA g<sup>-1</sup>. Superior cycling stability can be achieved in both capacity-limited (500 mAh g<sup>-1</sup>, 165 times at 400 mA g<sup>-1</sup>) and unlimited (ca. 3000 mAh g<sup>-1</sup>, 50 cycles at 800 mA g<sup>-1</sup>) modes.

# In-situ STM characterization of ionic liquids on Au(111) and HOPG electrodes in the presence of lithium salt

Xiao-Yan Hu, Jia-Wei Yan, Bing-Wei Mao

*State Key Laboratory of Physical Chemistry of Solid Surfaces, College of Chemistry and Chemical Engineering, Xiamen University, Xiamen 361005, China*  
jwyan@xmu.edu.cn

Ionic liquids (ILs) as electrolytes for lithium batteries have attracted considerable attention due to their unique properties such as wide electrochemical window, non-flammability, and thermal stability and environment friendly, which can lead to a great improvement in system safety<sup>[1]</sup>. Understanding the interfacial property of electrode/IL interface is extremely important for successful applications of ionic liquids in electrochemical energy devices<sup>[2]</sup>. In this article, we employ in-situ STM combined with electrochemical measurements to investigate the surface processes of Au(111) and HOPG electrodes in TFSI and FSI based ionic liquids containing 0.5 mol·L<sup>-1</sup> LiTFSI. On Au(111), the presence of the lithium salt has a predominant influence on the structure and property of the Au(111)/IL interfaces. Tremendous morphological changes occur upon cathodic potential excursion: formation of lithium oxide film corresponding to the reduction of oxygen in stage I; formation of loose monolayer film to highly faceted morphology as a result of the reduction of trace amount of water in stage II; initial stage of SEI formation in stage III as a consequence of the decomposition of ionic liquid, the deposition of lithium as well as the formation Au–Li alloying<sup>[3]</sup>. We mention that the CVs of Au(111) in different ionic liquids show similar characteristics and therefore we would expect that the formation of SEI on Au(111) in ionic liquids may be a common feature in the presence of lithium salt. On HOPG, the addition of Li salt can promote the decomposition of FSI anion and the formation of SEI in Py<sub>13</sub>FSI, and thus further suppress the intercalation of the cations and decomposition of the ionic liquid solvent to a certain extent. However, the SEI formed in Py<sub>13</sub>TFSI containing Li salt cannot efficiently passivate the surface so that large scale exfoliation of HOPG is still observed. The results imply that the chemical compositions of the SEIs in Py<sub>13</sub>FSI and Py<sub>13</sub>TFSI are considerably different, which critically influence the compatibility of the ionic liquids with graphite electrodes. In addition, trace amounts of oxygen and water can cause the formation of a film-like structure on Au(111), but show no apparent influence on HOPG.

# Effect of Electrode Composition on the Electrochemical Performance of the MnO Negative Electrode Materials for Li-ion Batteries

Duri Kim, Mina You, and Ji Heon Ryu\*

Graduate School of Knowledge-based Technology and Energy, Korea Polytechnic University  
Sangidaehak-ro, Siheung-si, Gyeonggi-do 429-793, Korea  
ryujh@kpu.ac.kr

Transition metal oxides ( $\text{MO}_x$ ,  $M = \text{Co}, \text{Fe}, \text{Mn} \dots$ ) are negative electrode active materials for high-capacity lithium-ion batteries because of their excellent lithium storage capability by conversion reaction. The  $\text{MO}_x$  has high theoretical specific capacity, however, it has very weak points of poor energy efficiency (both of the Coulombic and voltage efficiency) and low operating cell voltage due to the high reaction voltage of negative electrode.

$\text{MnO}$  is the promising transition metal oxide-based negative electrode material with high theoretical specific capacity of 740 mAh/g because of its low cost and relatively low reaction voltage, which is reversibly decomposed to metallic Mn and  $\text{Li}_2\text{O}$ .

In this study, we tried to investigate the electrochemical performance of MnO electrodes with the variation of particle size and electrode composition. The purchased MnO and ball-milled MnO (BM-MnO) were used as active materials for the variation of particle size. BM-MnO was prepared by planetary-mill with alumina ball and ethanol as dispersant for 1 hr with 350 rpm. The composite electrodes were prepared by coating the slurry of active material, PVdF (polyvinylidene fluoride) binder, and conducting aid (denka black) with 90:5:5, 80:10:10 and 70:15:15 compositions on a piece of Cu foil. The coin-type cell (CR2032) were assembled in a glove box with Li foil, 1 M  $\text{LiPF}_6$  in EC : EMC (3 : 7 in volume. ratio) as the electrolyte, and a PP separator. Electrochemical performances were evaluated by using battery cycler (WBCS3000).

Both the initial capacity and cycle performance of MnO were improved as the contents of carbon black increased regardless whether milling or not. Because the BM-MnO had smaller particle size and high surface area, it need more electronic pathways. Therefore, the BM-MnO showed under 300 mAh/g at both ambient and elevated temperature except the case of 15 % carbon black. The MnO materials went through the conversion reaction and converted to the nanosized Mn and  $\text{Li}_2\text{O}$ . The electrochemical performance might be strongly related at the electronic pathway as well as the particle size of metal oxide. And then, both the MnO and BM-MnO had very poor cycle performance at elevated temperature (60°C). The effect of electrode configuration on the high-temperature performance will be also presented.

Figure 1. Cycle performance of (a) MnO and (b) BM-MnO at room temperature.

# Improvement of High-Temperature Performance of the $\text{LiMn}_2\text{O}_4$ Positive Electrode by the Addition of $\text{Li}_3\text{PO}_4$

Min Young Hong, Hyojin Jung, and Ji Heon Ryu\*

*Graduate School of Knowledge-based Technology and Energy, Korea Polytechnic University  
Sangidaehak-ro, Siheung-si, Gyeonggi-do 429-793, Korea  
ryujh@kpu.ac.kr*

$\text{LiMn}_2\text{O}_4$  (LMO) has been attracted attention as the positive material of large-scale Li-ion batteries for EVs or ESS because of the characteristic of low cost and superior safety. However, its wide commercial use has been restricted due to the poor electrochemical performance at high temperature. Potential failure modes are the degradation of graphite negative electrode by the attack of Mn(II) ion dissolved from the LMO positive electrode. Therefore, most of the previous researches are focused on the inhibition of Mn dissolution from the LMO or the prevention of the electro-reduction of Mn(II) ion at the surface of the negative electrode.

In this study, we tried to remove the dissolved Mn ions in the electrolyte by the precipitation method. Also, we found that the addition of  $\text{Li}_3\text{PO}_4$  in the electrolyte could sharply reduce the concentration of Mn(II) ion. The Mn ions were expected to be precipitated to the  $\text{Mn}_3(\text{PO}_4)_2$  by the reaction with  $\text{PO}_4$  anions.

The standard LMO electrode was prepared with the LMO (Aldrich), carbon black (Super P), and polymeric binder (KF1100) in a weight ratio of 8:1:1. The 1 and 5 weight % of the  $\text{Li}_3\text{PO}_4$  were also added respectively to the mixture during the electrode preparation process. The addition of the  $\text{Li}_3\text{PO}_4$  improved the electrochemical performance at 60°C and the use of 1 weight %  $\text{Li}_3\text{PO}_4$  was the best because of the loss of initial specific capacity at the use of 5 weight %.

Figure 1. Cycle performance of  $\text{LiMn}_2\text{O}_4$  with  $\text{Li}_3\text{PO}_4$  additives at high temperature.

# **Silicon-carbon anode by plasma enhanced chemical vapor deposition for lithium-ion batteries**

The demand of high performance of Li-ion battery anode is increasing for the defense industry and livelihood. Recently, silicon-carbon composites were proposed to promote the electrochemical properties of Li-ion battery. Various technologies can be employed to fabricate Si-C composite for the anode of Li-ion battery. In this study, we tried to deposit Si films (from 240 nm to 960 nm) on the surface on carbon anode by plasma enhanced chemical vapor deposition (PECVD) at low temperature. We can find small amount of Si can improve the capacity of anode. As the thickness of Si thin film increase, we can get better charge-discharge performance of anode. First irreversible discharge capacity and second discharge capacity is very stable in compare with other Si-C anode materials. Besides, in repeatedly cycling test, the charge-discharge capacity did not drop quickly because of silicon. Our method does improve the volume expansion problem of Si-C composite anodes. The coulombic efficiency is higher than 85% for all samples. From the results of secondary electron microscopy (SEM) and Raman spectroscopy, the sample with Si thickness 960 nm has better electrical capacity and its surface has better protection for the carbon anode. From the electron probe microanalyzer (EPMA) analysis, we can find silicon deposited uniformly and the content increasing for longer deposition time. In conclusion, this research has proposed a creative method to prepare the anode of Li-ion battery. Our experiments have proved carbon anode with Si films by PECVD higher capacity and high coulombic efficiency for the anode of Li-ion battery.

# A Novel Air Electrode Comprising Core-Shell Particles for MH/Air Secondary Battery

Hideyuki Sano<sup>1</sup> and Masatsugu Morimitsu<sup>\*1,2</sup>

<sup>1</sup>Department of Science of Environment and Mathematical Modeling,

<sup>2</sup>Department of Environmental Systems Science,  
Doshisha University

1-3 Tatara-miyakodani, Kyotanabe, Kyoto 610-0394, Japan

\*E-mail: mmorimit@mail.doshisha.ac.jp

A metal hydride (MH)/air secondary battery consists of a gas diffusion electrode as the positive electrode, a hydrogen storage alloy as the negative electrode, and a KOH solution as the electrolyte. Oxygen in air reacts at the positive electrode during discharge, which means that the MH/air battery has no active mass stored in the positive electrode so that the weight and volume of the positive electrode are unnecessary to increase with increasing battery capacity. This is particular to this battery, since other air batteries have a limitation on the discharge capacity of the positive electrode because of the plugging by solid discharge product. From the reasons, we have been developing the MH/air secondary battery especially for high energy density applications such as electric vehicles. While in our previous studies, the conductive and catalyst-supporting material of the positive electrode was nickel powders, which have high durability in alkaline media and have shown a good cycleability for oxygen evolution and reduction [1], a further development is necessary for the positive electrode to reduce the weight and polarization for oxygen reactions. In this work, we tried to apply core-shell material to the positive electrode instead of nickel powders, which was nickel coated oxide particles and the oxide was smaller than nickel in density, in order to develop a novel positive electrode in combination with  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$  and PTFE. The preparation procedure and performance of the novel positive electrode were examined, and the MH/Air secondary battery using the developed positive electrode was assembled and evaluated.

The core-shell material was nickel coated silica particles and  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$  powders used as the bi-functional catalyst were prepared through co-precipitation in the solution dissolving  $\text{H}_2\text{IrCl}_6$  and  $\text{Bi}(\text{NO}_3)_3$  by addition of excess NaOH solutions, followed by calcination of the precipitates. These were mixed with PTFE and pressed onto a nickel mesh to form a sheet, and finally heated at 370 °C under nitrogen atmosphere to make the positive electrode. Cyclic voltammetry was performed to measure the polarization of the positive electrode with a three electrode cell in which one side of the positive electrode touched air and the other side faced 6 mol/L KOH solutions. The battery performance was further studied with using the MH negative electrode comprising  $\text{A}_2\text{B}_7$  type of hydrogen storage alloys. The negative electrode was produced by and supplied from FDK Co., Ltd.

The positive electrode comprising nickel coated silica particles was successfully developed, in which the oxide catalyst was loaded and dispersed on the core-shell particle well by the new method developed in this work. The oxygen reduction behaviors of the positive electrode were examined by cyclic voltammetry, and the result is shown with that obtained with the positive electrode using nickel powders [1], as shown in Fig. 1. The weight of the developed electrode was reduced by 48% compared to the previous nickel-based electrode, and the cathodic polarization was decreased in this study. The MH/Air secondary battery in this work also showed stable voltages for charge and discharge for more than 10 hours.

A metal hydride/air secondary battery is a new class of air battery, which consists of hydrogen storage alloy in the negative electrode in combination with alkaline aqueous solutions and the air electrode. This battery has a very unique property; no plugging by discharge product occurs on the positive electrode so that discharge capacity has no limitation on the positive electrode. This means that the battery capacity and energy density are significantly dependent of the capacity and capacity density of the negative electrode. In this study, the negative electrode with hydrogen storage alloys was modified in composition and activation process to improve the capacity and the capacity density, and then the MH/air secondary battery using the modified negative electrode was examined. We evaluated the capacity, capacity density, and MH utilization of the negative electrode and the cell voltage, capacity, and energy density of the battery to compare to our previous results [1].

MH negative electrodes were produced by and supplied from FDK Co., Ltd. and comprised a porous nickel matrix containing an  $A_2B_7$  type of hydrogen storage alloy and a binder, in which the electrode size (4.0 cm x 4.6 cm, 0.52 to 0.73 mm in thickness) are almost the same as the previous ones [1]. The capacity of the MH electrode was varied with the amount and weight ratio of hydrogen storage alloy. The activation process of the negative electrode was carried out with changing the charge-discharge rate, the overcharge ratio, and others. For this experiment, the MH electrode was placed and pressurized between two  $Ni(OH)_2$  electrodes with 6 mol/L KOH solutions. The MH/air battery was assembled in a PTFE container, in which from the bottom to the top, there were the negative electrode, the membrane separator with 6 mol/L KOH solutions, and the positive electrode. The positive electrode was the mixture of graphite as conductive material,  $Bi_2Ir_2O_{7-z}$  as bi-functional catalyst, and PTFE as binder, which was the same as the previous one [1].

Some parameters of the activation process of the MH negative electrode influenced on the practical discharge capacity, the MH utilization, and the polarization during charge and discharge. The optimization of such parameters was done and the activated negative electrodes achieved 1.8 Ah, 1,929 Ah/L, and 301 Ah/kg (labeled as NE-A) or 2.3 Ah, 1,707 Ah/L, and 279 Ah/kg (labeled as NE-B), which were improved in capacity or capacity density compared to the previous results [1]. Figure 1 shows the comparison of discharge curves of MH/air secondary batteries using the negative electrodes of NE-A and NE-B in this study and that of the previous study. While the discharge voltages of these three batteries are almost the same in Fig. 1, the discharge capacity is increased in the batteries developed in this study. The energy densities were 868 Wh/L and 126 Wh/kg (with NE-A) and 825 Wh/L and 130 Wh/kg (with NE-B), and the high capacity battery with NE-B discharged 2.19 Ah. The volumetric energy density of 800 Wh/L is beyond the theoretical one of lithium ion secondary battery (LIB), and the results obtained in this study has proven that the MH/air secondary battery has a higher potential in energy density than LIB.

Fig. 1 Comparison of discharge curves of MH/Air secondary batteries at 0.1 C.

# Durable Mesoporous Core-Shell Lithium Titanate-Carbon Composite as Anode in Lithium ion Batteries

Chi-Ying Vanessa Li\*, Ching-Kit Ho, Zhao-Feng Deng and Kwong-Yu Chan<sup>^</sup>

Department of Chemistry, The University of Hong Kong,

Pokfulam, Hong Kong

\* [cyvli@hku.hk](mailto:cyvli@hku.hk), <sup>^</sup> [hsccky@hku.hk](mailto:hsccky@hku.hk)

Lithium titanate, particularly  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  has been applied as viable anode materials in Li-ion batteries due to its good structure stability. [1-3] Present material forms lack mesoporous structures and surface area for reactions, restricting the energy and power densities of Li-ion battery system. With the high discharge rate performance limited by the low electronic conductivity of the material ( $< 10^{-11} \text{ Sm}^{-1}$ ), addition of carbon is one of the effective way in enhancing the rate performance and operation temperature range. [1]

In this study,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ -carbon composites were synthesized by impregnation of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  into hollow core mesoporous shell hierarchical carbon of controlled dimensions. These  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ -carbon composites benefit from higher electronic conductivity, increased surface area of the active material and possibly length scale effect. With controlled structure of HCMS in terms of hollow core diameter, thickness of the shell and diameter of the mesopores, the electrochemical behavior of mesoporous  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ -carbon composite was optimized.

(left) TEM image of the starting precursor – hollow core mesoporous shell carbon; and (right) Schematic diagram of nanoparticles of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  embedded in the HCMS carbon with controllable structure (diameter of hollow core (C), thickness of the mesoporous shell (S), and pore diameter ( $d_p$ ); red dots are  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  nanoparticles).

A metal/air battery is one of the promising candidates for next generation secondary battery, because of high theoretical energy density over a lithium ion secondary battery (LIB), although no metal/air secondary battery has achieved such high performance in operation so that the development of the air secondary batteries utilizing a variety of negative electrode's materials (Li, Na, Ca, or Mg) is in progress. A novel rechargeable air battery has been also investigating by our group, which uses hydrogen storage alloy in the negative electrode with concentrated KOH solutions and the discharge and charge reactions are water generation and decomposition [1]. The positive electrode's reactions are oxygen reduction and evolution during discharge and charge, and the polarization of the positive electrode significantly depends on the bi-functional oxygen catalyst, which was pyrochlore type of composite oxide,  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$  in our previous work [1]. In this study, another pyrochlore oxide,  $\text{Bi}_2\text{Ru}_2\text{O}_{7-z}$ , was applied to the oxygen catalyst, and the preparation, characterization, and performance of the oxide catalyst were investigated. The positive electrode and MH/air battery using the catalyst were also developed to examine the output performance and compare to the previous one using  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$ .

$\text{Bi}_2\text{Ru}_2\text{O}_{7-z}$  was prepared through co-precipitation in the solution containing  $\text{RuCl}_3$  and  $\text{Bi}(\text{NO}_3)_3$  by adding NaOH solutions, followed by calcination of the precipitates. In the procedure, the concentration of NaOH, calcination temperature and time, and others were changed, and the obtained oxide for each condition was characterized by XRD, SEM, and EDX. The positive electrode comprising the oxide catalyst, Ni powders, and PTFE was prepared and the polarization behaviors were examined. The MH/air secondary battery consisted of the MH negative electrode supplied by FDK, the positive electrode, and the separator with KOH solution. The battery was operated with constant current at ambient temperature without air or oxygen flow to the positive electrode.

The obtained oxides were  $\text{Bi}_2\text{Ru}_2\text{O}_{7-z}$  without byproduct when the examined firing temperature ranged from 500 °C to 800 °C, while the concentration of NaOH showed some effects on crystallographic structure and particle size of the oxide. The particle size of  $\text{Bi}_2\text{Ru}_2\text{O}_{7-z}$ , which was 20-50 nm, was smaller than that of  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$  prepared at the same temperature and NaOH concentration in our previous study [1]. The positive electrode was fabricated using the oxide catalyst at different composition ratios from 10 wt% to 30 wt%, a fixed ratio (10wt.%) of PTFE, and nickel powders in balance, and the results on polarization for oxygen reduction and evolution during discharge and charge revealed that 25 wt.% of oxide was recommended, for which the positive electrode presented lower polarization for both  $\text{O}_2$  reactions than that with  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$ . Furthermore, the possible discharge current of the MH/air secondary battery with  $\text{Bi}_2\text{Ru}_2\text{O}_{7-z}$  developed in this study was 900 mA in maximum and the output power density achieved 174 W/L, which was better than that with  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$  [1], as shown in Fig. 1.

A metal/air secondary battery is expected as one of the next generation energy storage devices which could achieve a high energy density, since the positive electrode uses oxygen in air so that the discharge capacity theoretically depends only on the negative electrode. While many efforts have been done to realize this battery, it has been known that the discharge product of the air battery using less noble metals such as lithium and magnesium induces the plugging of the positive electrode, resulting in a small discharge capacity, a difficulty of a high current operation, and a poor cycleability. We have been also developing a different type of air battery from them, which comprises the negative electrode using hydrogen storage alloys in combination with an alkaline aqueous electrolyte, and our previous studies on the battery performance showed stable charge and discharge voltages and an improvement in power density [1]. However, a high capacity density of MH electrode is needed to further improve an energy density and a high rate performance. In this paper, we report an improvement in energy density of the MH/air secondary battery with using the negative electrode comprising  $A_2B_7$  type of hydrogen storage alloys with some modification in their composition and structure.

The negative electrode (MH electrode) used  $A_2B_7$  type of hydrogen storage alloys, Ni powders, and polyethylene powders, which were mixed and pressed to make a sheet of *ca.* 45 mm x 45 mm. Charge-discharge behaviors of the negative electrode were studied using a three-electrode cell equipped with the Hg/HgO reference electrode. The positive electrode (air electrode) was consisted of nickel powders as a conductive and catalyst-supporting material,  $Bi_2Ir_2O_{7-z}$  powders as a bi-functional catalyst, and a PTFE binder.  $Bi_2Ir_2O_{7-z}$  powders were prepared through the co-precipitation and calcination process; equimolar  $H_2IrCl_6 \cdot 6H_2O$  and  $Bi(NO_3)_3 \cdot 5H_2O$  were dissolved in water and then the precipitates obtained by adding excess NaOH solutions in the metal salt solution under oxygen bubbling, followed by washing, drying, and heating at 370 °C in  $N_2$  atmosphere. The MH/air secondary battery using these electrodes and 6 mol/L KOH solutions was operated at constant current at *ca.* 25 °C without air or oxygen flow to the positive electrode.

The discharge capacity of the improved negative electrode was about 1.8 Ah, which corresponded to the capacity density of 1789 Ah/L and 287 Ah/kg. The polarization behaviors of the negative electrode at different states of charge indicated that the negative electrode's resistance was *ca.* 0.2  $\Omega$ , irrespective of SOC. Figure 1 shows the charge-discharge curves of the MH/air secondary battery, in which the stable charge and discharge voltages are seen and the average voltages are *ca.* 1.56 V and *ca.* 0.79 V, respectively. The energy densities calculated from this result, which is based on the total volume or weight of the battery's components, are 779 Wh/L and 106 Wh/kg. The battery was able to operate at 1100 mA (83 mA/cm<sup>2</sup>) in maximum with no plugging, and the maximum power and power density were found to be 316 mW and 193 W/L.

This work was financially supported by "Advanced Low Carbon Technology Research and Development Program (ALCA)" of Japan Science and Technology Agency (JST). The authors also acknowledge FDK Co., Ltd. for supplying the MH negative electrode.

# Synthesis of $\text{NaTi}_2(\text{PO}_4)_3$ thin-film and electrochemical behavior in aqueous solutions

Fumihiro Sagane

Department of Electronics and Materials Science, Graduate School of Engineering, Shizuoka University,  
3-5-1 Johoku, Naka-ku, Hamamatsu, Shizuoka, 432-8011, Japan  
e-mail sagane.fumihiro@shizuoka.ac.jp

$\text{Na}^+$ -ion secondary batteries have been paid much attention as the post  $\text{Li}^+$ -ion secondary batteries, due to their much abundant Na-resources. So far, we have found that the  $\text{Na}^+$ -ion transfer at the solid/organic solution interface was faster than that of  $\text{Li}^+$ -ion[1]. Therefore,  $\text{Na}^+$ -ion batteries are expected to exhibit high power by using highly ionic conductive aqueous solutions, although the energy densities is inferior to  $\text{Li}^+$ -ion batteries. In the present study,  $\text{NaTi}_2(\text{PO}_4)_3$  negative electrode reported by Okada, et.al. is focused[2]. In order to catch the electrochemical behavior clearly, the thin-film electrode without binders is synthesized and their electrochemical behavior in the aqueous solution is discussed.

$\text{NaTi}_2(\text{PO}_4)_3$  thin-film was synthesized by sol-gel method. The sol of  $\text{NaOC}_2\text{H}_5$ ,  $\text{Ti}(\text{OC}_3\text{H}_7)_4$ ,  $\text{P}_2\text{O}_5$  and ethanol was spin coated on the quartz substrate, and then the substrate was sintered at 1273 K under  $\text{O}_2$  flow condition.  $\text{NaTi}_2(\text{PO}_4)_3$  preparation was confirmed by X-ray diffraction and Raman spectroscopy, although a trace of  $\text{TiO}_2$  impurity was observed. From the scanning electron microscopy (SEM), the closely dispersed submicrometer-sized particles were observed, as shown in Fig 1. For the electrochemical measurements, carbon coat was conducted on the thin-film surface, which works as the conductive additives and current collectors. Cyclic voltammogram of the thin-film electrode in  $0.2 \text{ mol dm}^{-3} \text{ Na}_2\text{SO}_4(\text{aq})$  showed the sharp reduction and oxidation peak around at  $-0.8 \text{ V}$  (vs. $\text{Ag}/\text{AgCl}$ ), corresponding to the  $\text{Na}^+$ -ion insertion and extraction, respectively. Figure 2 shows the impedance spectrum of the thin-film electrode at  $-0.8 \text{ V}$ . One semi-circle was clearly observed and the semi-circle showed the electrode potential dependency. Therefore, we can conclude the semi-circle ascribes to the charge transfer resistance of  $\text{Na}^+$ -ion. From the temperature dependency of the interfacial resistance, the activation energy corresponding to the  $\text{Na}^+$ -ion insertion/extraction was calculated to be  $26 \text{ kJ mol}^{-1}$ . The result was much smaller than that of  $\text{Li}^+$ -ion transfer at the electrode/organic solution interface and which means the aqueous  $\text{Na}^+$ -ion batteries are expected to be high power. In the poster presentation, the  $\text{Na}^+$ -ion diffusion in the electrode materials will be also discussed.

Fig.1 SEM image of the  $\text{NaTi}_2(\text{PO}_4)_3$  thin-film

Fig.2 Complex impedance plot of  $\text{NaTi}_2(\text{PO}_4)_3$  thin-film in  $\text{Na}_2\text{SO}_4(\text{aq})$  at  $-0.8 \text{ V}$ .

$\text{LiFePO}_4$  is one of the promising cathode material for lithium-ion batteries as it exhibits high chemical stability and relatively high rate performance.<sup>[1]</sup> The origin of the high rate performance exemplified in  $\text{LiFePO}_4$  should provide design principles for further development of high rate cathode materials. The (dis)charge reaction of  $\text{LiFePO}_4$  proceeds through a two phase behavior between Li-rich  $\text{Li}_{1-x}\text{FePO}_4$  (LFP) and Li-poor  $\text{Li}_x\text{FePO}_4$  (FP). Under high rate cycling, we revealed the metastable phase formation of  $\text{Li}_{0.6}\text{FePO}_4$  ( $\text{L}_x\text{FP}$ ) which acts as a buffer layer between Li-rich phase (LFP) and Li-poor phase (FP).<sup>[2]</sup> However, the detailed reaction between LFP and FP during high rate cycling has not been fully understood due to short lifetime of metastable  $\text{L}_x\text{FP}$  phase. To investigate the phase transition mechanism, with respect to  $\text{L}_x\text{FP}$  phase, cycling was conducted at elevated temperatures because  $\text{L}_x\text{FP}$  is thermodynamically stable above 200°C.<sup>[3]</sup> The electrolyte used was a binary molten salt based on  $\text{MN}(\text{SO}_2\text{CF}_3)_2$  (M=Li, Cs). Herein, we demonstrate a two-step (dis)charge potential plateau in  $\text{LiFePO}_4$  upon cycling at 230°C. The phase transition behavior is investigated by using *operando* time-resolved X-ray Diffraction (TR-XRD) at various temperatures.

Charge tests were performed using three-electrode cells at 170°C and 230°C. The working electrode comprised a mixture of carbon-coated  $\text{LiFePO}_4$ , acetylene carbon black, and polyimide binder (90:5:5(wt%)) coated on Al foil current collectors. Li-Al alloy wires were used as the counter and reference electrodes.

Conventional single charge plateau curve is observed at 170°C, while the charge curve at 230°C shows two plateau regions. An initial low potential plateau indicates the phase transition of LFP to  $\text{L}_x\text{FP}$ , and the second higher potential plateau indicates the phase transition of  $\text{L}_x\text{FP}$  to FP. *operando* XRD measurements conducted at 230°C reveal the formation of  $\text{L}_x\text{FP}$  phase during the charge process.

We will also show the phase transition behavior of  $\text{LiFePO}_4$  at lower temperature regions, and discuss the origin of the high rate performances of  $\text{LiFePO}_4$ .

Lithium ion batteries are the leading candidate for energy storage devices in electric vehicles due to their high energy and power density. However, drawback of lithium ion batteries is reduced energy and power densities at low temperatures<sup>[1]</sup>. One of the major factors is considered to be the effective ionic conduction in composite electrode which might cause poor performance at low temperature. Unfortunately, it is difficult to distinguish the electronic conductivity and the ionic conductivity in composite electrodes. Therefore, the effect of ionic conductivity in composite electrode is not well understood. In this study we introduce the measurement method for simultaneous measurement of effective electronic and ionic conductivities in composite electrodes to clarify the temperature dependence of effective ionic conductivity in composite electrodes.

The electrochemical cell which contains 6 probes connecting with the LiFePO<sub>4</sub> composite electrode was used. For the electronic and the ionic conduction electrodes, Al foils and Li foils were used, respectively. Two potentiostats and bias voltage were connected to the cell. After open circuit voltage is measured, the two potentiostats were operated with this voltage as the set point. And then, a bias voltage was applied between the two working electrodes. The ionic and electronic current was measured by current meters. The measurement principle is explained in the literature.<sup>[2]</sup>

Figure 1 shows the reported ionic conductivity of LiPF<sub>6</sub> / EC : EMC (3:7 wt)<sup>[3]</sup> and the effective ionic conductivity in the composite electrodes (LiFePO<sub>4</sub> : Acetylene Black : PVDF = 80:5:15 wt) measured in this study. The temperature dependence of ionic conductivity obeys the Vogel-Tammann-Fulcher (VTF) equation<sup>[3]</sup>:

$$\sigma = AT^{-1/2} \exp[-B/(T-T_0)],$$

where  $A$ ,  $B$  and  $T_0$  are constant, apparent activation energy and the temperature at which the conductivity becomes zero. The apparent activation energy of bulk electrolyte is 3.12 kJ / mol and that in the composite electrode is 4.14 kJ / mol. One of possibility causing larger activation energy in composite electrodes is high viscosity in low temperature. The high activation energy in composite electrode results in poor rate performance at low temperature.

# **Modified Carbon Felt via a Facile Oxidation Treatment as an Efficient Electrode for a Vanadium Redox Flow Battery**

Heng-Wei Chiang\*, Chao-Yen Kuo, Chien-Hong Lin, Hwa-Jou Wei\*

*Institute of Nuclear Energy Research*

*No. 1000, Wenhua Rd., Jiaan Village, Longtan District, Taoyuan City 32546, Taiwan (R.O.C.)*

*hengwei@iner.gov.tw*

Carbon felt is commonly used in vanadium redox flow batteries (VRFB) as electrode material. Through electron transfer, the active substances in the electrolyte solution undergo a redox reaction. This study investigated the process of carbon felt by using a facile oxidation method. FT-IR, contact angle and XPS were measured to confirm functional groups (-OH, -COOH) were on the surface of our material. In addition, hydrophilicity was improved, leading to the improvement of charge transfer. At a current density of 80 mA/cm<sup>2</sup>, energy efficiency of the VRFB was increased by 2%–3% comparing with that using untreated carbon felt. Therefore, oxidation of carbon felt is proved to be a simple, rapid, and effective way to enhance the performance of battery while excluding external influences on the environment.

# Adventures in Dioxygen Electrochemistry

Iain Aldous\*, Laurence Hardwick

Department of Chemistry, Stephenson Institute for Renewable Energy, University of Liverpool,  
Liverpool, L69 7ZF, UK

\*i.m.aldous@liv.ac.uk and hardwick@liverpool.ac.uk

The study of chemistry and electrochemistry of dioxygen in non-aqueous electrolyte is essential for unlocking the potential of alkali metal-oxygen batteries that have high theoretical specific energies ( $\text{Li-O}_2$  3505  $\text{Wh Kg}^{-1}$ ,  $\text{Na-O}_2$  1581  $\text{Wh Kg}^{-1}$  and  $\text{K-O}_2$  2820  $\text{Wh Kg}^{-1}$ ).<sup>1-3</sup> Recent attention on these systems have emphasised the chemical sensitivity of dioxygen in the presence of lithium, water and solvent donor number and potential dependent subtle changes within electrolyte configuration at the oxygen-cathode interface.<sup>4, 5</sup> The employment of spectroelectrochemistry that probe electrode interfacial regions is required to understand the role of each component of the dioxygen cathode interface and their effects on dioxygen reduction and oxygen evolution reactions (ORR/OER). This will ascertain the conditions necessary to produce a practically viable and electrochemically reversible oxygen cathode. Presently our comprehension of the effect of changing the alkali metal cation size on the ORR/OER mechanism and electrode interface effects remains incomplete. Recent work on the effects of changing the size of tetraalkylammonium supporting conductive salts has already displayed changes in kinetics of ORR on glassy carbon and gold electrodes.<sup>6</sup> Our presentation here will focus on our continued study into understanding the interfacial effects of changing alkali metal cation size on the oxygen cathode interface for alkali metal-oxygen batteries.

[changcc@itri.org.tw](mailto:changcc@itri.org.tw)

The development of electric vehicles (EVs) is an inevitable trend in the future. The core technology of the EVs is battery which directly affects the driving distance of EVs. According the roadmap of NEDO, the target for driving distance per charging is 200 km in 2020, 500 km in 2030. Thus the weight energy density of the battery, respectively, must reach the 250Wh / Kg in 2020 and 500Wh / Kg in 2030. It is 3-5 times higher than those batteries in used, and safety would be a critical issue when the development of electrode material focuses on increasing energy by utilizing cathodes and anodes with either high capacity or high voltage. But the common used liquid electrolyte can't meet the demand because of narrow electrochemical window, dissolution of active materials from the cathode, flammable problem, and so on. Although a lot of research efforts have been devoted to developing new electrolytes system to solve above problems, but it is still difficult to address the above problems simultaneously. The solid state electrolyte may be a good candidate among various solutions. However, the several problems of developing solid-state battery needed to overcome. For example, the ionic conductivity of solid electrolyte in room temperature is too low; high impedance interface affect charge-discharge efficiency; the energy density and stability of batteries is poor; the compatibility of lithium metal is poor leading to passivation and safety concerns after prolonged operation.

In this post, research focuses on highly conductive solid electrolyte membrane, high-energy composite cathode and active anode with multiple protection technologies. By this sophisticated technologies, we present a novel architectures of high energy solid-state batteries which would be ideal for use in EVs.

# SEI stabilizer agent epicyanohydrin for cathodes used in LIBs

Arailym Nurpeissova<sup>1</sup>, Da-In Park<sup>2</sup>, Sung-Soo Kim<sup>1</sup>

<sup>1</sup> *Graduate School of Energy Science and Technology, Chungnam National University, Daejeon 305-764, Republic of Korea*

<sup>2</sup> *SK Innovation Co., Daejeon 305-712, Republic of Korea*

*Araiko1987@gmail.com*

The use of epicyanohydrin as an additive to a LiPF<sub>6</sub> salt-based electrolyte in 1:1:1 EC:EMC:DMC was investigated as a potential candidate for high-power lithium-ion batteries operated at 60 °C. Epicyanohydrin polymerized to form a thermally stable, thin, conductive, and evenly distributed protective film on the cathode surface, preventing the dissolution of the cathode material LiNi<sub>0.6</sub>Co<sub>0.2</sub>Mn<sub>0.2</sub>O<sub>2</sub> and suppressing interfacial impedance, and thereby protecting the surface from further reaction with the electrolyte at 60 °C. It was demonstrated that the cycling performance of the cathode material with the additive was enhanced due to the formation of the epicyanohydrin-derived polymer SEI.

<sup>2</sup>Office of Society-Academia Collaboration for Innovation, Kyoto University, Uji, Gokashou, Kyoto, 611-0011, JAPAN  
shoma.ida.25n@st.kyoto-u.ac.jp

Morphological optimization of composite electrodes is one of the most crucial factors to the performance of lithium ion batteries, and therefore the guideline for the preparation of composite electrodes is important. One of the factors governing battery performance should be reaction distribution in composite electrodes. The reaction distribution, which arises in the depth direction of the electrode, decreases power density and causes degradation. In our previous work, the existence of reaction distribution in the LiFePO<sub>4</sub> composite electrodes was observed experimentally by using 2D imaging X-ray absorption spectroscopy. When the porosity of the composite electrode was low, the reaction distribution was observed clearly.<sup>[1]</sup> However, it is still difficult to directly observe the dynamics of reaction distribution in composite electrodes. The purpose of this study is to verify the reaction distribution based on the Newman model simulation.<sup>[2]</sup> In addition, we discuss a numerical estimation of the parameter that is difficult to determine experimentally, such as the effective diffusion coefficients of the electrolyte in the heterogeneous porous electrodes.

The simulation was performed for the discharge reaction of LiFePO<sub>4</sub> at a rate of 10 C until 0.45Li insertion. Insertion of Li into the active material was depicted as a shrinking-core model. The effective electronic and ionic conductivities of the composite electrodes were measured by simultaneous measurement<sup>[3]</sup> and used in the simulation. The diffusion coefficient of the electrolyte used in the simulation was compensated with Bruggeman's equation.<sup>[2]</sup>

The reaction distribution obtained from the simulation shows an agreement with the experimental results when the porosity parameter is set to be larger value than the measured value. This means that the effective diffusion coefficients of the electrolyte in the heterogeneous porous electrodes is larger than the compensated values with Bruggeman's equation in homogeneous media. Considering that the measured effective ionic conductivities are also larger than the compensated values with Bruggeman's equation as shown in Fig. 2, these discrepancies between ideal and actual values can originate from the heterogeneity of the pores in the electrodes.

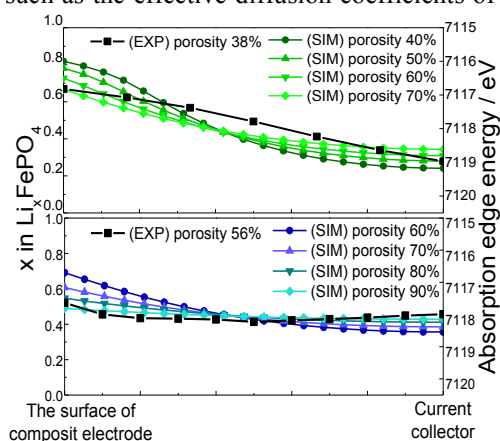

Fig.1. Experimental and numerical reaction distribution in composite electrode, discharged at a rate of 10 C

Fig.2. Ionic conductivity in composite electrodes that was measured by simultaneous measurement

A dimensional stability of SnO<sub>2</sub> nanoparticles during Li<sup>+</sup> insertion/de-insertion was improved by confining them within a highly crosslinked graphene framework. The composite was prepared by reacting an optimal amount of benzene-1,4-diboronic acid (BDBA) with SnO<sub>2</sub>-anchored graphene oxide (SG) having a high density of oxygen functionalities, which was introduced by irradiating ozone on as-synthesized SG. The resultant composite (SGF) possessed a high boron/carbon ratio and a low fraction of unreacted boronic acid groups, indicating a high crosslinking density of a framework. The highly crosslinked SGF showed an excellent stability at a high capacity level when cycled between 0.1 and 3.0 V vs. Li/Li<sup>+</sup>. Further decrease of a low-end potential limit induced the instability of boronic ester linkage. The SGF delivered capacities greater than 940 mAh·g<sup>-1</sup> after 150 cycles at 200 mA·g<sup>-1</sup>, exhibiting a fading rate of 1.3 mAh·g<sup>-1</sup>·cycle<sup>-1</sup> (from 2<sup>nd</sup> to 150<sup>th</sup> cycles). This was distinctly contrasted with 10.4 mAh·g<sup>-1</sup>·cycle<sup>-1</sup> for SGF prepared without ozone-treatment and cycled between 0.01 and 3.0 V vs. Li/Li<sup>+</sup>. The rate capabilities of SGF were also comparable to or better than those in previous reports for SnO<sub>2</sub>/graphene composites, implying that a highly crosslinked nature of SGF does not hamper the electroactivity of SnO<sub>2</sub>.

## **Introduction**

The theoretical energy density of Li metal (2062 Ah L<sup>-1</sup>) is much greater than those of rechargeable anodes in the present lithium ion batteries (e.g. graphite, < 1000 Ah L<sup>-1</sup>). Controlling Li plating/stripping reactions is thus important for next-generation-battery technologies with Li metal anodes such as all-solid-state-lithium batteries (SSLB) and Li-air batteries. Inorganic solid-state electrolytes blocks Li dendrite growth, which is always a critical problem in organic liquid electrolytes. Particularly, amorphous electrolyte plays a key role in suppress the Li growth toward the cathode. Previous work studied the Li plating/stripping reactions with lithium phosphorous oxynitride (LiPON) coated with a Cu current collector (CC) [1]. This study focuses on Li nucleation and growth behaviors at Pt-CC/LiPON interfaces as compared to non-alloying CCs (e.g. Cu) using *in-situ* scanning electron microscopy (SEM).

## **Experimental**

The top and bottom of a Li<sub>1.3</sub>Al<sub>0.3</sub>Ti<sub>1.7</sub>(PO<sub>4</sub>)<sub>3</sub> (LATP) sheet (1.25 × 1.25 cm<sup>2</sup>, Ohara Co.) were coated with 2.5-μm-thick LiPON layers by magnetron sputtering. A CC film (Cu, Pt) was deposited on the top LiPON surface by pulsed laser deposition (PLD). The CC area was controlled to be 5.0 mm in diameter. A Li film with a diameter of 9.0 mm was deposited on the LiPON surface on the bottom by vacuum evaporation. An all-solid CC/LiPON/LATP /LiPON/Li cell was sandwiched with Cu and brass plates. The Cu plate has a viewport in the center. Li electrodeposition was performed under galvanostatic conditions. Current densities were estimated for the whole area of a CC with a diameter of 5.0 mm.

## **Results & Discussion**

Figure 1 shows a voltage transient during Li electrodeposition at 100 μA cm<sup>-2</sup> with a 30-nm-thick Pt CC. In the stage A (Li-Pt alloying), no Li particles appear on a Pt CC in contrast to the case with a Cu CC. However, numerous Li particles suddenly appear when the voltage decreases to the negative peak (stage B). Figure 2 shows surface SEM images after Li electrodeposition at 50–1000 μA cm<sup>-2</sup> with Pt CCs of 30 nm in thickness. The number density of Li particles increases with increasing current density. Li islands never coalesce with each other even at 1000 μA cm<sup>-2</sup>. We will discuss the difference in mechanism of Li metal nucleation and growth between Cu and Pt CCs.

Silicon-based carbon composite is a potential alternative anode material for high-energy density Li-ion batteries due to higher theoretical specific capacity of silicon than commercialized graphite and appropriate operation voltage. However, the major drawback of the commercialization of silicon-based anode material is a short cycle life originated from volume change of silicon during lithiation/delithiation and electrical and mechanical disintegration of particles. A variety of challenges to acquire a good performance is on going in order to overcome those issues. One of the most promising approaches is the control of electrode-electrolyte interfacial reaction for the formation of a stable solid electrolyte interphase (SEI), on the basis of a fundamental understanding of interfacial reaction mechanisms. Utilization of electrolyte additives, modification of surface property of active material, etc. have been researched to improve the interfacial stability. In this presentation, we report the interfacial reaction behavior of silicon and its carbon-delivered anodes, and its correlation to their cycling characteristics.

# Anion Conductivities of Positively-charged Hydroxides with One-dimensional Channel Framework

Rui Di, Kohei Miyazaki, Tomokazu Fukutsuka, Takeshi Abe  
Graduate School of Engineering, Kyoto University, Nishikyo-ku, Kyoto 615-8510  
[dirui@elech.kuic.kyoto-ac.u.jp](mailto:dirui@elech.kuic.kyoto-ac.u.jp)

In this work, a hydroxide  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl}_{1-x}\text{OH}_x \cdot 2\text{H}_2\text{O}$  with one-dimensional channel framework structure has been synthesized hydrothermally. In order to investigate the anion conductivity of this compound, we carried out anion exchange using KOH solution, and  $\text{Yb}_3\text{O}(\text{OH})_6\text{OH} \cdot 2\text{H}_2\text{O}$  was obtained. We measured the anion conductivities of these two compounds by A.C. impedance spectroscopy. We evaluated the influences of temperature and relative humidity on the anion conductivity of  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl}_{1-x}\text{OH}_x \cdot 2\text{H}_2\text{O}$ .

## 1. Introduction

Electrolyte is an important factor which can influence the performance of batteries or sensors. Generally, liquid electrolytes have relatively higher ion conductivities and are frequently used in almost all batteries. But, there are also some problems to be improved, such as electrolyte leakage and the limitation of operating temperature. To solve these problems, the development of solid electrolytes is required. In this work, we focused on an one-dimensional channel framework structure hydroxide  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl} \cdot 2\text{H}_2\text{O}$  which has a cationic framework and an ability for anion-exchange reactions with small ions. Therefore, it can be expected as an anion conductor. We investigated the conductivity of these compounds by A.C. impedance spectroscopy.

## 2. Experimental

$\text{Yb}_3\text{O}(\text{OH})_6\text{Cl} \cdot 2\text{H}_2\text{O}$  was synthesized by hydrothermal method [1] and anion exchange was successfully made by reacting  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl} \cdot 2\text{H}_2\text{O}$  with KOH aqueous solution. We added polytetrafluoroethylene (PTFE) as a binder in  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl}_{1-x}\text{OH}_x \cdot 2\text{H}_2\text{O}$  powder and pressed into a pellet. The pellets were used for the A.C. impedance measurement using amplitude of 20 mV and frequency range of  $1 \times 10^6$ –1 Hz. The conductivity of  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl} \cdot 2\text{H}_2\text{O}$  was also measured using an amplitude of 100 mV and a frequency range of  $1 \times 10^6$ –1 Hz.

## 3. Results and Discussion

From the Nyquist plots of  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl}_{1-x}\text{OH}_x \cdot 2\text{H}_2\text{O}$ , a semi-circle was observed and its size showed the dependence of temperature and relative humidity. Therefore, we ascribed the resistance component to ionic conductivity through positively-charged hydroxide. An activation energy derived from the Arrhenius plots of the ion conductivity of  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl}_{1-x}\text{OH}_x \cdot 2\text{H}_2\text{O}$  was calculated (shown in Fig.1). The value is  $25.1 \text{ kJ mol}^{-1}$  which was larger than the activation energy of alkaline electrolyte [2]. Therefore, there were higher energy barrier of ion transportation in solid electrolyte.

The result of electrochemical impedance measurement of  $\text{Yb}_3\text{O}(\text{OH})_6\text{Cl} \cdot 2\text{H}_2\text{O}$  also showed that the feasibility as a chloride ionic conductor, but it is necessary to be improved further in its conductivity.

## Introduction

Lithium-ion batteries have been used in EVs due to their high energy densities. However, lithium-ion batteries possess some problems to be solved for the further improvement. One of them is the enhancement of rate capabilities. The rate of lithium-ion batteries is influenced by several factors such as ion diffusion in the composite electrodes, charge transfer resistances, diffusion in the active materials, etc. Among them, we have studied the charge transfer resistances. The charge transfer resistances are inverse proportion to the frequency factor and  $\exp(-E_a/RT)$ , where  $E_a$ ,  $R$ , and  $T$  denote to the activation energy, gas constant, and absolute temperature. Therefore, the decrease of the charge transfer resistances can be made by the increase of the frequency factors and the decrease of  $E_a$ . As for the negative electrodes of lithium-ion batteries, graphite electrodes have been mainly used. Hard carbon electrodes have been also used in HEVs since the rate performance is superior to that of graphite. This will be principally due to the large frequency factors. Then, we have focused on the surface treatment of hard carbon electrodes to decrease the activation energy of  $E_a$ . Here, we report the electrochemical properties of surface-treated hard carbon electrodes by  $\text{Li}_3\text{PO}_4$ .

## Experimental

Glassy carbon electrodes were used as model electrodes in this study. In advance, the glassy carbon electrodes have been heat-treated at 773 K in the air for 1 h. Surface treatment of the glassy carbon electrodes was made by the sputtering of  $\text{Li}_3\text{PO}_4$  by the several conditions. Three-electrode cell was fabricated by using surface-treated glassy carbon electrode as a working electrode and lithium metal for counter and reference electrodes. Electrolyte solution was  $1 \text{ mol dm}^{-3} \text{ LiClO}_4 / \text{EC} + \text{DEC} (1:1)$ . Cyclic voltammograms were conducted with a potential range of 0 – 3 V at a scan rate of 1 mV/s. Ac impedance spectra of the glass carbon electrodes were measured at given potentials and temperatures.

## Results and discussion

Cyclic voltammograms (Fig. 1) of the surface-treated glassy carbon showed the large reductive and oxidative currents which corresponded to the insertion and extraction of lithium-ion at the electrode, respectively. In addition, it was found that the surface-treatment enhanced the glassy carbon electrode properties by comparing the pristine one. Fig. 2 shows Nyquist plots at various potentials. As is observed in Fig. 2, various semi-circles were seen. Assignment of each semi-circle will be discussed in the conference.

**Fig. 1** Cyclic voltammograms of surface-treated glassy carbon and pristine glassy carbon in  $1 \text{ mol dm}^{-3} \text{ LiClO}_4/\text{EC}+\text{DEC} (1:1)$ .

**Fig. 2** Impedance spectra of surface-treated glassy carbon in  $1 \text{ mol dm}^{-3} \text{ LiClO}_4/\text{EC}+\text{DEC} (1:1)$  at potential of 0.4 V.

# Operando X-ray absorption spectroscopic study on magnesium metal anode reaction for magnesium rechargeable battery

hattori.masashi.27r@st.kyoto-u.ac.jp

Magnesium rechargeable batteries have paid attention for next generation batteries because of their high theoretical capacity, safety, and abundance. As the electrolytes for magnesium batteries, Grignard reagents have been mainly used<sup>[1]</sup>. However, the stability of the electrolytes in high potential and their corrosive nature are major problems. In recent years, magnesium deposition/dissolution in magnesium inorganic salts with ether-based solvents have been reported<sup>[2]</sup>. For the further development of electrolyte for magnesium batteries, reaction mechanism at electrolyte/magnesium metal interface should be elucidated. In this study, bulk structure of electrolyte is investigated by Raman spectroscopy, X-ray absorption spectroscopy (XAS) and the theoretical calculation. And then, we develop *operando* soft X-ray measurement system for magnesium battery and apply to the analysis of electronic and local structure of electrolyte during magnesium deposition.

Cyclic voltammetry(CV) was conducted in a three-electrode cells. Then different electrolytes are used; 1) 0.5 M magnesium bis(trifluoromethane sulfonyl) amide (Mg(TFSA)<sub>2</sub>)/triglyme, 2) 0.5 M Mg(TFSA)<sub>2</sub>/2-MeTHF, 3) 0.25 M Mg(AlCl<sub>2</sub>EtBu)<sub>2</sub>/THF. Platinum plate and magnesium rod were used as working electrode and counter electrode, respectively. The structures of bulk were analyzed by XAS measurements. *Operando* XAS measurements were performed at different potential during magnesium deposition. Mg K-edge XAS measurements were carried out at the beam line BL27SU at SPring-8 (Japan).

While magnesium deposition/dissolution is observed in (Mg(TFSA)<sub>2</sub>)/triglyme, magnesium is not deposited in Mg(TFSA)<sub>2</sub>/2-MeTHF. Fig. 1 shows local structural changes around magnesium in magnesium deposition process in 0.5 M Mg(TFSA)<sub>2</sub>/triglyme electrolyte. When the potential is lowered, decrease in the peak intensity and peak from magnesium metal were observed. The decrease of peak intensity reflects the desolvation process of triglyme.

## Introduction

All-solid-state lithium secondary batteries using inorganic solid electrolytes instead of liquid electrolytes have been expected as next-generation secondary batteries with high safety and high reliability. Among the inorganic solid electrolytes, sulfide-based solid electrolyte such as  $\text{Li}_2\text{S-P}_2\text{S}_5$  based glass solid electrolyte has received much attention due to the high lithium-ion conductivities and room temperature pressure sintering<sup>[1]</sup>. Graphite has been used as the negative electrode materials in lithium-ion batteries, but little work of graphite in sulfide solid electrolyte has been done<sup>[2]</sup>. We focused on the interfacial reaction between graphite and sulfide solid electrolyte, which will play a main role on the rate capability of all-solid-state batteries. Here we report lithium-ion transfer at the interface between graphite negative electrode and sulfide-based glass electrolyte.

## Experimental

A three-electrode cell was assembled by using graphite sheet (76  $\mu\text{m}$ ) as working electrode, lithium metal as counter and reference electrodes, and a layered electrolyte consists of 75 $\text{Li}_2\text{S}$ -25 $\text{P}_2\text{S}_5$  glass pellet and 1  $\text{mol dm}^{-3}$   $\text{LiClO}_4$ /propylene carbonate (PC). Cyclic voltammetry and electrochemical impedance spectroscopy were carried out.

## Results

Figure 1 shows the cyclic voltammogram of graphite sheet. An oxidation-reduction current was observed between 0 – 0.5 V (vs.  $\text{Li/Li}^+$ ). Since lithium ion cannot intercalate into graphite sheet in  $\text{LiClO}_4/\text{PC}$ , this oxidation-reduction peak indicates that lithium-ion intercalation/de-intercalation proceeded at the interfacial between graphite sheet and 75 $\text{Li}_2\text{S}$ -25 $\text{P}_2\text{S}_5$  glass pellet. In the Nyquist plot, one semi-circle was observed and assigned to interfacial lithium-ion transfer process. In the meeting, the activation energy for the interfacial lithium-ion transfer process will be discussed.

**Fig. 1** Cyclic voltammogram of graphite sheet at the 7th cycle.

We report on low temperature behavior of electrodes based on their loading amount, thickness and packing density for Li ion batteries consisting of graphite/ $\text{LiNi}_{0.6}\text{Co}_{0.2}\text{Mn}_{0.2}\text{O}_2$  cells.

In order to investigate the main factors to limit low temperature operation of LIBs, three types of cells, coin-type half cells, coin-type full cells and pouch-type full cells were prepared. Also, discharge capacity and capacity retention, using coin type full cell were comparatively studied both at room temperature (25°C) and low temperature (-32°C).

Electrochemical impedance spectroscopy and galvanostatic technique were used for understanding the low temperature performance of the cells.

Samples having a lower loading exhibited better capacity retention than those in the case of a higher loading due to the limited Li-ion diffusion within the thicker electrodes.

The design of a LIB for using low temperature environment must be carried out on the basis of a comprehensive understanding of crucial structural & material parameters such as electrode thickness or active material loading.

## Introduction

Increasing concerns about environmental and energy problems accelerate the demands for high-energy-density batteries. Lithium-ion batteries (LIB) have large energy densities and have been well

known for their long cycle life (EV). However, the short distance. Present LIBs are used in order to shorten the distance between the electrodes are used. Graphite composite electrodes with high power densities, designed. Unfortunately, to understand the ion transport through the graphite intercalation between the ion

## Introduction

Zinc is an ideal material for use as a negative electrode in batteries, showing high specific capacity and high reducing power. However, significant morphological changes of the zinc electrode during its oxidation-reduction cycles, such as dendrite growth and shape changes, have limited the development of zinc-based secondary batteries [1]. To observe the morphological changes associated with capacity degradation, application of *in situ* battery analytical methods is promising. In this study the zinc electrode behavior was examined by X-ray fluorescence (XRF) imaging [2] to capture the zinc distribution near the electrode and X-ray diffraction (XRD) mapping to visualize the shape changes during cycling. The dissolution of the zinc species affecting the rechargeability of the zinc electrode is demonstrated.

## Experimental

The distribution of zinc species near the electrode was evaluated by projection-type XRF imaging in reflection geometry. Zinc deposition on a copper working electrode (WE) followed by its dissolution was employed in ZnO containing 4 M KOH using a zinc plate as a counter electrode (CE). The XRF images near Zn-K absorption edge (9.8 keV) were recorded every 5 s using a two-dimensional detector. The shape change of the ZnO composite electrode were monitored by XRD mapping in a transmission mode with ca. 900 pixels per electrode. Both experiments were employed at BL28XU, SPring-8 (Hyogo, Japan).

## Results and Discussion

The XRF imaging shows dissolved zinc species in the electrolyte before the reduction (Fig. 1(a)), and then zinc-rich zone near the working electrode with hydrogen bubbles during the reduction (Fig. 1(b)). At the end of the reduction, many pillar-like deposits, namely dendrite, are visible (Fig. 1(c)). A concentrated zinc zone containing the bubbles is seen on oxidation (Fig. 1(d)), indicating the formation of soluble zinc species, presumably in supersaturation. The observation of the zinc species in supersaturated solutions by XAFS and NMR would provide useful information.

The XRD mapping indicates the loss of ZnO at the edge and the growth in the center of the electrode in the course of cycling, showing typical shape change phenomena. It is shown that the shape change causing the capacity loss is closely related to the zinc solubility in the electrolyte, implying the importance of fixation of zinc species at the electrode for better rechargeability.

In order to develop bulk-type all-solid-state-lithium batteries (SSBs), fabrication techniques for composite films with dense electrodes and solid electrolytes are required. However, a highly resistive reaction layer forms at the electrode/solid electrolyte interface in some material systems when the electrode and solid electrolyte are sintered together at high temperature [1]. Here, we focus on aerosol deposition (AD) which is a ceramic film fabrication technique that operates at room temperature [2]. In this work, we prepared composite films composed of  $\text{LiNi}_{1/3}\text{Co}_{1/3}\text{Mn}_{1/3}\text{O}_2$  (NMC) and highly  $\text{Li}^+$  conductive solid electrolyte by AD and examined their charge-discharge properties as SSBs.

Mixed powders composed of NMC (D50 = 10  $\mu\text{m}$ ) and  $\text{Li}_{1+x}\text{Al}_y\text{Ti}_{2-y}\text{Si}_x\text{P}_{3-x}\text{O}_{12}$  (LATP) (D50 = 0.5  $\mu\text{m}$ ) at a predetermined weight ratio were used as starting materials for AD. These mixed powders were jetted to Si and  $\text{Li}_7\text{La}_3\text{Zr}_2\text{O}_{12}$  (LLZ) by AD [3]. AD films were characterized by XRD, FE-SEM, and TEM. Lithium films were deposited on the other side of LLZ from which the AD films are formed by vacuum evaporation. Charge-discharge measurements of resultant SSBs (Li/LLZ/NMC-LATP) were carried out in an Ar-filled glove box using a constant current then constant voltage (current taper).

Fig. 1a shows a cross-sectional SEM image of an AD film with a weight ratio of NMC:LATP=20:1 on Si. From EDX analysis, black and white regions in the SEM image correspond to LATP and NMC, respectively. Hence, NMC and LATP were uniformly dispersed in the AD film. Fig. 1b shows a TEM image of a NMC/LATP interfacial region of the film. Nano-size voids were densely filled with LATP. Only XRD peaks associated with Si, NMC, and LATP were observed in AD films, and no XRD peaks originating from a reaction layer of a sintered mixture of NMC and LATP were observed. Therefore, it is considered that AD films were fabricated without any heating.

Fig. 2 shows charge-discharge curves of a SSB at 100 °C. The charge current density was kept constant at 50  $\mu\text{A cm}^{-2}$  (i.e. 1/10C), and the discharge current density was varied from 50-1000  $\mu\text{A cm}^{-2}$ . The charge curves after 2 cycles show the same profile regardless of discharge current density. The discharge capacity at a 3-V cutoff with 50  $\mu\text{A cm}^{-2}$  was 135  $\text{mAh g}^{-1}$ , which corresponded to 90% of capacity in liquid electrolyte [4]. Finally, the discharge capacity was 17  $\text{mAh g}^{-1}$  at a 3-V cutoff with 1000  $\mu\text{A cm}^{-2}$ . Charge-discharge reactions were carried out over 90 cycles, and discharge capacity maintained 97% of the first cycle. It is expected that the highly  $\text{Li}^+$  conductive glass ceramic LATP serves to conduct  $\text{Li}^+$  and inhibit crack spreading associated with volume change of the active material, resulting in stable charge-discharge reactions.

We report the performance of all solid state (ASS) Li ion battery with composite sulfide solid electrolyte. First, Li-P-S sulfide electrolyte by high energy ball milling was prepared. Then, 5 types of composite sulfide solid electrolytes were made using ball-milled Li-P-S sulfide and PEO (10. 20. 30. 40, 50 wt%). Here, LiClO<sub>4</sub> salt (ratio of 1/18) was used in order to enhance Li conductivity of PEO polymer.

In order to measure Li conductivity of Li-P-S or composite sulfide solid electrolytes, test cell was prepared with 2032 coin cell holder.

Li conductivity of high energy ball milling Li-P-S sulfide electrolyte was approximately  $1 \times 10^{-3}$  S/cm. With increasing amount of PEO, Li conductivity of composite sulfide solid electrolyte decreased upto approximately  $1 \times 10^{-5}$  S/cm.

The electrochemical performance of all solid state Li ion battery with Li-P-S or composite sulfide solid electrolytes will be discussed.

# Facile Synthesis of CuO Nanochains as Anode Materials for Lithium-Ion Batteries

CuO, one of the transition-metal oxides, is considered a very appealing anode material for next generation advanced lithium-ion batteries. However, its practical application is hindered due to the rapid capacity decay resulting from the mechanical pulverization and large volume variations during Li<sup>+</sup> insertion and extraction.

The polycrystalline CuO nanochains were fabricated by a facile wet-chemical method. The BET specific surface area and BJH pore volume are 123.1 m<sup>2</sup> g<sup>-1</sup> and 0.82 cm<sup>3</sup> g<sup>-1</sup> respectively. SEM and TEM results suggest that the CuO nanochains are composed of nanoparticles with size of 8nm. The electrochemical result indicates that the one-dimensional structure may also contribute to the enhanced rate performance. The assembled nanochain structure endows it with high rate capacities of 710, 680, 600, 530 and 390 mAh g<sup>-1</sup> at charge/discharge rate of 0.1C, 0.2C, 0.5C, 1C and 2C, exhibiting a higher capacity and better rate performance as anode material.

z.bakenov@nu.edu.kz

Due to its high theoretical capacity of 1672 mAh g<sup>-1</sup> and high energy density of 2600 Wh kg<sup>-1</sup> sulfur is a very attractive candidate as a cathode material for rechargeable lithium battery [1-2]. However, most works on both LIBs and Li/S batteries still rely on conventional liquid organic carbonate solution as the preferred electrolyte, which intrinsically has many drawbacks including volatility, flammability and potential leakage, which are triggering the safety issues [3]. Therefore, the search for safer and more reliable electrolyte systems is urgent and polymer electrolytes are promising candidate in this regard. Poly(ethylene oxide)-based solid polymer electrolytes are common examples of safe electrolyte. However, since they are limited by low ion conductivity at ambient temperature, the development of novel gel electrolytes which entraps large amount of liquid electrolyte attracts big interest.

In this work we develop novel composite gel polymer electrolytes (GPEs) with high conductivity, high organic solvent uptake and high thermodynamic and mechanical stability for lithium/sulfur batteries by addition of ceramic filler into polymer matrix. The composite GPEs are fabricated allowing for facile transport of Li<sup>+</sup> ions but preventing leakage of electrolyte solution contained within the polymer membrane structure. Such GPE electrolytes have three unique features: electrolyte solution immobilization during battery cycling and rapid lithium ion transport. Furthermore, addition of functionalized natural and synthetic clay nanoparticles as ceramic filler allows overcoming the main problem of GPE – the loss of their mechanical strength when they are plasticized. Polymer nanocomposites uniquely combine the properties of inorganic and organic components providing the opportunities to develop novel advanced materials.

We have combined polymers and co-polymers (e.g., PMMA, PAN, P(AN-co-MMA), PVDF-HFP) with typical and novel Li-ion containing salt solutions (e.g., LiPF<sub>6</sub>, LiClO<sub>4</sub>, LiCF<sub>3</sub>SO<sub>3</sub>, and Li<sub>2</sub>B<sub>12</sub>F<sub>12-x</sub>H<sub>x</sub> dissolved in organic solvents). Among the inorganic layered hosts, montmorillonite (MMT) offers high aspect ratio, high cation exchange capacity, large specific surface area, appropriate interlayer charge. We have used functionalized with amino- and carboxyl-groups MMT and hallosite clay nanoparticles. A Li/S polymer cell containing a composite GPE, consisting of a solution of LiPF<sub>6</sub> in EC/DMC/DEC dispersed in (PVDF-HFP)/(PMMA)/MMT matrix, has exhibited a good cycling performance. This system is under investigation with evaluation of polymer matrices, the modification of nanoclays and their ratio in the composite electrolyte.

## Abstracts:

Compared with the commercial non-aqueous polyvinylidene difluoride (PVDF) binder, the water soluble binder featuring environmental-friendly, low cost, and high safety is highly desirable for adhesive industry in lithium-ion batteries (LIBs). Carboxymethyl chitosan (CCTS)-poly (ethylene oxide) (PEO) was firstly reported as a water-soluble binder for 5 V  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode in Li-ion batteries. CCTS/PEO blends at different mass ratios are characterized by Fourier transform infrared (FTIR) spectroscopy, X-ray diffraction (XRD), and Differential Scanning Calorimetry (DSC) analysis. The electrochemical performance of  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode with CCTS/PEO blend binder was investigated and compared with the commercial non-aqueous polyvinylidene difluoride (PVDF).  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode using CCTS/PEO blend binder with an optimized ratio of (0.85/0.15, by mass) exhibited better cycling stability and lower ohmic resistance than that of PVDF.

Renewable energy has become an important terminology in our era. Electrochemical energy storage devices play an important role in utilizing renewable energy, which is efficient and economic. The most urgent issue is developing robust batteries with long lifespan in deep charge-discharge condition. Among all electrochemical power sources, lead-carbon battery is one of the most promising technologies to be used in large scale renewable energy storage [1]. Lead-carbon battery, a ramification of traditional lead acid battery, has got fast development in the past decade especially in the application of hybrid electrical vehicles [2]. Nevertheless, lead-carbon battery faces great challenges in the application in renewable energy storage. The elaboration of the mechanism of activated carbon in lead-carbon battery will help us design more effective Pb-C bi-material structures and battery composed thereof.

In this study, we demonstrate that activated carbon (AC) contributes little capacitive capacity via electrical double layer capacitor in the charge process. However, AC contributes hydrogen adsorption pseudo-capacitance and it is the electrodeposition of Pb on the surface of AC that dominates the charge process of AC lead-carbon electrode.

Besides, the hydrogen evolution reaction (HER) on AC is prohibited by the reversible hydrogen adsorption at high charge rates. While, at low charge rates, the current efficiency of lead-carbon electrode decreases due to HER on AC.

**Fig. 1** Schematic diagram of the mechanism of activated carbon in lead-carbon electrode.

Carbon materials with various morphologies and structures have been extensively investigated for the anode materials of lithium ion batteries (LIBs) [1]. Graphite is widely adopted due to its natural abundance and high stability. Nevertheless, graphite has a low theoretical capacity of  $372 \text{ mAh g}^{-1}$ , which is unsuitable for applications needing high power and energy. Hierarchical porous carbon (HPC) has been researched for lithium ion batteries, due to its high reversible lithium capacity and fast lithium storage kinetics [2]. HPC is usually prepared from template methods, which is complicated and expensive. Lignin is an abundant natural ingredient in the world. Lignin-based products can effectively reduce the demand of fossil fuel and is beneficial for a sustainable society. Recently, lignin based hierarchical porous carbons (LHPCs) have been prepared by various template methods, and are mainly investigated for electrode materials in supercapacitors. The preparation of LHPCs from a facile method is valuable, and the use of LHPCs as anode materials in lithium ion battery is attractive.

In this paper, hierarchical porous carbon derived from lignin (denoted as LHPC) was prepared via a facile method. The obtained LHPC was composed of unique 3D macroporous network with mesopores and micropores decorated on carbon walls. The LHPC displayed a stable, high capacity of  $386 \text{ mAh g}^{-1}$  after 560 galvanostatic charge-discharge cycles at a current density of  $500 \text{ mA g}^{-1}$ . Furthermore, LHPC displayed high cycling stability and perfect rate capability.

**Fig. 1** Schematic diagram of the lithium ion storage in LHPC, and the galvanostatic charge-discharge cycling performance of LHPC/Li half-cell at a high current density of  $500 \text{ mA g}^{-1}$ .

yishiuan@mail.mcut.edu.tw

The novel composite polymer membrane was fabricated via electrospinning and solution-casting methods. The polymer composite membrane is consisted of three component layers, i.e., two PVDF-HFP layers plus a middle layer of PET nanofiber nonwoven, with a PVDF-HFP/PET/PVDF-HFP sandwich structure (Fig. 1). The characteristic properties of the composite polymer membranes were studied by SEM, XRD, TGA, micro-Raman spectroscopy, galvanostatic charge-discharge test, and impedance spectroscopy. The ionic conductivity and the electrolyte uptake of the conventional PE separator and the composite polymer membrane were also examined and compared (Table 1). It was found that the ionic conductivity can be achieved  $\sim 10^{-3}$  S cm<sup>-1</sup>; the electrolyte uptake was  $\sim 282$  wt.%. The LiFePO<sub>4</sub>/Li cells with the PE separator and the composite polymer membrane were assembled and examined. Fig. 2 shows that the overall cells with the composite polymer membrane exhibit higher discharge capacities than those with the PE separator at 0.2C~10C rates (e.g.,  $Q_{sp,ave}$ : 148.4 vs. 140.9 mAh g<sup>-1</sup> at 0.2C rate). In Fig. 3, we found that the capacity retention of the composite polymer membrane at 1C/1C rate for 200 cycles was  $\sim 80.1\%$ ; however, only 73.5% for the PE separator. We also found that the coulombic efficiencies of the cells with the composite polymer membrane and the PE separator were 99.7% and 96.7%, respectively. According to the results, it was discovered that the electrochemical performances of the composite polymer membrane are much better than those of the PE separator. It was demonstrated that the composite polymer membrane with a sandwich structure is a promising separator for lithium-ion batteries [1-3].

[jkchang@ncu.edu.tw](mailto:jkchang@ncu.edu.tw)

In this work, Na<sub>0.44</sub>MnO<sub>2</sub> and hard carbon are used as the cathode and the anode, respectively, in a sodium-ion battery. At first, the NaMnO<sub>2</sub>/Na half cell and the hard carbon/Na half cell are studied both in conventional ethylene carbonate/diethyl carbonate mixed electrolyte containing 1 M NaClO<sub>4</sub> and in N-propyl-N-methylpyrrolidinium bis(fluorosulfonyl)imide ionic liquid electrolyte with 1 M sodium bis(fluorosulfonyl)imide. In the ionic liquid electrolyte, the Na<sub>0.44</sub>MnO<sub>2</sub> and hard carbon electrodes can show reversible capacities of 115 mAh/g and 280 mAh/g, respectively. Based on the obtained electrochemical properties, a Na<sub>0.44</sub>MnO<sub>2</sub>/hard carbon full cell with the ionic liquid electrolyte is constructed. A satisfactory high-rate capability and excellent cyclic stability are recognized. Because the high thermal stability, low volatility, and low flammability of the ionic liquid electrolyte, high safety and good durability of the cell are warranted. The proposed cell could have great potential for practical applications.

# A quantitative analysis on the failure mechanism of nano-Si electrode and the effect of fluoroethylene carbonate

seungoh@snu.ac.kr

Silicon has emerged as an alternative negative electrode material to conventional carbonaceous materials because of its high capacity and low working potential. However, its commercialization has been hindered by low Coulombic efficiency and poor cycle performance. The low Coulombic efficiency is because of irreversible consumption of  $\text{Li}^+$  ions and electrons during charge/discharge. Because  $\text{Li}^+$  ions are supplied from the positive electrode and their total amount is limited, the continuous irreversible reactions induce capacity degradation of cell.

On Si negative electrode, there are two major routes for the irreversible reactions; reductive electrolyte decomposition and Li trapping. These irreversible reactions are deeply associated with severe volume change during cycling. Repeated volume change causes crack formation within the Si particles. Then, the new Si surface is exposed to the electrolyte solution, and subsequently the electrolyte is reductively decomposed on the surface. The volume change also weakens contact between particles. Therefore inserted  $\text{Li}^+$  ions and electrons cannot be released from the Li-Si alloy phases due to the contact resistance. It is called Li trapping.

In this research, two irreversible reactions on nano-Si electrode are quantitatively divided by a novel calculation model. The lithiation/de-lithiation capacities and QOCV(quasi-open circuit voltage) after lithiation step are used for the calculation. The QOCV is converted to depth of charge with capacity unit by using GITT(galvanostatic intermittent titration technique) experiment for the calculation of the capacity only consumed for Li-Si alloy formation.

Then, the model is applied to the nano-Si electrode with two different electrolyte systems; EC/DEC solvent and with FEC(fluoroethylene carbonate). The irreversible reaction capacities are divided successfully by the model and the two electrolyte systems represent definitely different aspects. In EC/DEC solvent system, continuous electrolyte decomposition and large amount of Li trapping is observed. The accumulated electrolyte decomposition products constitute a thick layer and then, facilitate the contact loss between particles.

In FEC co-solvent system however, both of irreversible capacities are alleviated. The suppressed electrolyte decomposition induces very thin SEI layer and the electrically conductive network is well maintained after long cycles. Therefore the failure behavior in EC/DEC solvent system is prevented, which results in a better Coulombic efficiency and cycle performance.

Increasing demand for lighter, more powerful batteries has driven research into alternative battery technologies. One system that has received significant attention is the Lithium-Oxygen battery. This system exploits the reduction of oxygen by lithium metal, forming lithium peroxide, to provide a theoretical specific energy of  $3500 \text{ Wh kg}^{-1}$ . One of the major problems facing the Lithium-Oxygen battery is the passivation of the air electrode caused by insoluble lithium oxides and lithium carbonate blocking access to the pores. These products are not completely oxidized on charging and therefore accumulate within the electrode causing the capacity to fade with each cycle.

This work focuses on identifying solution based catalysts in non-aqueous electrolytes to facilitate the oxidation of these insoluble products. The catalysts are oxidized at a higher potential than the lithium peroxide but undergo much faster electron transfer. Once oxidized the catalyst is able to oxidize any lithium peroxide/ lithium carbonate remaining, unblocking the pores and retaining the cells capacity over subsequent cycles. The figure below displays cyclic voltammetry of oxygen reduction and evolution with (black) and without (red) a catalyst. This demonstrates that that incorporation of such a catalyst can have a significant effect on reducing cell passivation dramatically improving the cycle life of the cell.

Figure 1: Cyclic voltammetry at  $50 \text{ mV s}^{-1}$  of a two electrode cell containing a glassy carbon working electrode (3mm) and Lithium foil counter/ reference electrode under an oxygen atmosphere. The electrolyte consisted of diglyme containing  $0.1 \text{ M LiTFSI}$  with (black) and without (red) a catalyst.

# **W<sup>6+</sup>&Br<sup>-</sup>-codoped Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub> Anodes with Super Rate Performance**

*Q.Y. Zhang (qianyuzhang@ms.giec.ac.cn); C.Y. Ouyang (cyouyang@hotmail.com); L.Z. Zhang (lzzhang@ms.giec.ac.cn)*

**Abstract:** We report a novel Li<sub>4</sub>Ti<sub>5-x</sub>W<sub>x</sub>O<sub>12-x</sub>Br<sub>x</sub> (x=0.025, 0.050 and 0.100) anode material simultaneously doped with W<sup>6+</sup> and Br<sup>-</sup> ion prepared by a simple solid-state reaction in air, aiming to significantly improve its electrical conductivity of Li<sub>4</sub>Ti<sub>5</sub>O<sub>12</sub>. Our theoretical calculation predicts that codoping with W<sup>6+</sup> on the Ti<sup>4+</sup> site and Br<sup>-</sup> on the O<sup>2-</sup> site can remarkably narrow down the band gap, and thus facilitates the electron transport in the lattice of LTO. The comparative experiments prove that W&Br-codoped LTO exhibits higher electrical conductivity compared with undoped LTO as expected, thus improved rate capability and specific capacity. Particularly, Li<sub>4</sub>Ti<sub>5-x</sub>W<sub>x</sub>O<sub>12-x</sub>Br<sub>x</sub> (x=0.05) exhibits the best rate capability and cyclic stability with an outstanding capacity retention of 88.7% even at 10 C rate after 1000 cycles. This codoping strategy with high valance transition metal and halide ions holds promise to be applied to other insulating cathode materials suffering from inferior electrical conductivity.

# Synthesis and characteristics of hyper-branched oligomer directly coated on high voltage cathode material in lithium ion battery

Recently, a hyper-branched bismaleimide oligomer (so called STOBA) was utilized as an electrode additive for lithium ion batteries [1]. It was reported that STOBA increases the battery safety and decreases the irreversibility of electrochemical reaction due to the coating of oligomer on electrode's surface. According to the literatures [2], N,N'-4,4'-diphenylmethane-bismaleimide (BMI) was attempt to enhance the high voltage performance for lithium-ion batteries. When 0.1 wt% of BMI added into the control electrolyte, the high voltage cycling performance of LiCoO<sub>2</sub> is improved evidently while charging up to 4.5 V rather than the conventional 4.2 V.

In this study, the epoxy acrylate (EA) is used to replace and compare with the BMI in order to precisely define and control the reaction mechanism of STOBA. Two kinds of STOBAs, the BMI and barbituric acid (BTA) and the EA and BTA, are chosen for directly reaction with Al doped LiCoO<sub>2</sub>. In this investigation, BTA is used to react with BMI and EA thermally. Hence, the reactions will be performed under typical temperature that permitted the BTA to generate free radicals. At the end of process, we will compare the formed oligomers by characterized them into fourier transform infrared spectroscopy (FT-IR), gel permeation chromatography (GPC), thermogravimetric analysis (GPA), differential scanning calorimetry (DSC) and electrochemical (EC) properties.

## ■ Introduction

As the market of electric vehicle (EV) is expanded gradually, the characteristics of lithium ion batteries (LIB) such as high energy density, high power, and safety are considerably emphasized. Silicon is promising anode due to higher theoretical capacity ( $\text{Li}_{15}\text{Si}_4$ ,  $3579 \text{ mA h g}^{-1}$ ) compared to that of graphite ( $\text{LiC}_6$ ,  $372 \text{ mA h g}^{-1}$ ). Because of poor cycle performance, many studies related to silicon have focused on improvement of capacity by reducing volume expansion, whereas there have barely been studied about thermal behavior of silicon-based anode. Herein we report failure mechanism of SiO negative electrode by storage at  $85^\circ\text{C}$

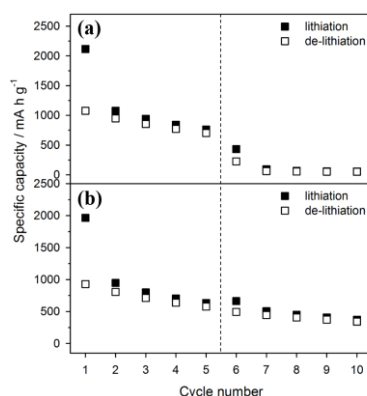

## ■ Experimental

SiO (325mesh, Sigma Aldrich) was mixed with super-P and PVdF (70:20:10 wt. ratio) and a slurry was coated on copper foil. The 2032-typed coin cell was assembled in an Ar-filled dry box with Li counter electrode and  $1.3 \text{ M LiPF}_6$  dissolved in a mixture of ethylene carbonate (EC) and diethyl carbonate (DEC)=3:7 (vol. ratio). The galvanostatic discharge/charge cycling was made at  $320 \text{ mA g}^{-1}$  in the potential range of  $0.040\sim 1.5 \text{ V}$  (vs.  $\text{Li/Li}^+$ ). After 5 cycles, cell was stored at  $85^\circ\text{C}$  for 24 h with de-lithiated state. And then cell is moved to room temperature and recycled. EIS, FE-SEM, XPS were examined to understand electrochemical phenomenon.

## ■ Results and discussion

Capacity of SiO negative electrode rapidly decreases after  $85^\circ\text{C}$  storage. Compared with non-thermal storage, unknown failure mechanism occurs during thermal storage. OCV of SiO negative electrode during thermal storage continuously increase. This means that SEI of SiO negative electrode induced by EC decomposition is damaged during thermal storage [1]. In order to repair SEI, additional electrolyte decomposition occurs permanently during thermal storage. SEI is getting thicker and thicker due to repetitive damage and repair process during thermal storage. As a result, Li ion undergoes kinetic barriers by large resistance caused by thick SEI after thermal storage.

The detailed electrochemical results will be reported in the meeting.

**Figure 1.** Cycle performance of SiO negative electrode (a) with  $85^\circ\text{C}$  storage for 24 h, (b) without storage.

# Environmentally friendly binders for lithium ion batteries

Nicholas Löffler<sup>1,2</sup>, Guk-Tae Kim<sup>1,2</sup>, Diogo Vieira Carvalho<sup>1,2</sup>, Stefano Passerini<sup>1,2</sup>

<sup>1</sup>Karlsruhe Institute of Technology (KIT), P.O. Box 3640, 76021 Karlsruhe, <sup>2</sup>Helmholtz Institute Ulm (HIU), Helmholtzstraße 11, 89081 Ulm

[Nicholas.loeffler@kit.edu](mailto:Nicholas.loeffler@kit.edu)

In view of limited crude oil resources and climate endangering emissions (e.g. CO<sub>2</sub>) deriving from the consumption of fossil fuels, lithium ion battery technology is currently facing a new great challenge: its implementation in large-scale devices like (hybrid) electric vehicles and stationary energy storage to balance the intermittent supply of renewable energy sources such as wind, solar and tidal [1-3].

In contrast to the sustainable and “green” character of the energy to be stored, today’s commercially available rechargeable lithium ion batteries cannot be considered as particular “green” energy storage systems. Therefore, continuously growing research efforts are focusing on the utilization of environmentally benign battery components (e.g. active materials, binders, separators) to manufacture “greener” and more sustainable lithium ion batteries [4-6].

In this sense, we focus in our work on the replacement of today’s most widely used binder – solvent system: polyvinylidenedifluoride (PVdF), which is dissolved in N-methyl pyrrolidone (NMP). Although PVdF exhibits excellent physical and electrochemical properties as binder for electrodes, it suffers of a few clearly recognizable drawbacks, among which toxicity of the solvent, end-of-life disposal (no easy recycling) of the polymer and high costs of materials and processing, are of major importance [4]. Therefore, it is desired to substitute the PVdF/NMP system with water-based binder systems, which are environmentally friendly and less costly [5].

A major drawback of aqueous processing (e.g. with carboxymethyl cellulose (CMC) as binder) of metal oxides as active materials is the corrosion (due to increasing pH) of the aluminium current collector and consequently inferior electrochemical performances [7]. We report on several approaches to simultaneously avoid corrosion issues and guarantee mechanical properties which allow the processing of water-based electrode formulations. In this regard we focus on the investigation of additives, enabling the aqueous processing of electrodes with electrochemical performances comparable to the conventional PVdF/NMP system. Moreover, we are researching a new group of water soluble polymers as binder for lithium ion batteries. We concentrate on a basic understanding of the interaction between the active material and the binder polymers as well as the influence of the above mentioned additive.

The electrodes containing different polymeric binders are studied concerning electrochemical properties and cycling performance in half- and full- cells. The influences of different additives/polymers are investigated with SEM, XPS and IR techniques.

The electrochemical performances of aqueous based-electrodes using an acidic solution as additive in the manufacturing process are in a comparable range with organic solvent based cathode and anode electrodes.

# Enhanced Li-air batteries using redox mediator

Seon Hye Yoon, Chan Kyu Lee and Yong Joon Park

*Department of Advanced Materials Engineering, Kyonggi University,  
San 94-6, Iui-dong, Yeongtong-gu, Suwon-si, Gyeonggi, 443-760, Korea  
yjpark2006@kyonggi.ac.kr*

Development of next generation energy-storage system is one of the greatest challenges of the modern society because the commercial batteries cannot meet the requirement for large scale applications such as electric vehicles. Li/air batteries have attracted enormous research attention as promising next generation energy-storage system due to their high theoretical energy density. However, they are still facing several bottlenecks to overcome before practical applications.

Basic reaction of the non-aqueous Li/air batteries is formation of  $\text{Li}_2\text{O}_2$  on discharging and dissociation of that on charging ( $\text{Li}^+ + \text{O}_2 \rightleftharpoons \text{Li}_2\text{O}_2$ ) on the surface of air electrode [1-3]. One of the major issues is that the dissociation of solid and insulating  $\text{Li}_2\text{O}_2$  is not so fast and efficient because of kinetic limitation attributed to the poor electron transport between the  $\text{Li}_2\text{O}_2$  particles and the electrode surface. This feature of non-aqueous Li/air batteries results in undesirable electrochemical properties such as large over-potential, low rate-capability, and limited cyclic performance. An interesting approach to alleviate these problems is introduction of redox mediator as an electron-hole transfer agent to facilitate the dissociation of  $\text{Li}_2\text{O}_2$  [4-5]. The redox mediator can replace the slow reaction between insulating  $\text{Li}_2\text{O}_2$  particles and the solid electrode surface with the fast reaction between redox mediator ( $\text{M}/\text{M}^+$ ) and  $\text{Li}_2\text{O}_2$  particles, which leads to efficient dissociation of reaction products and reduced over-potential. In this study, we proposed multi-functional redox mediator as a new strategy to enhanced Li/air batteries. The cell using multi-functional redox mediator presented enhanced electrochemical performance, which indicated that it could be an effective new approach for superior Li-air batteries.

# Physiochemical characteristics of graphene nanosheets affecting their electrochemical Na<sup>+</sup> storage properties

Xu-Feng Luo, Chueh-Han Wang, Cheng-Hsien Yang, and Jeng-Kuei Chang\*  
*Institute of Materials Science and Engineering, National Central University*  
No. 300, Jhong-da Rd., Taoyuan, 32001, Taiwan  
[jkchang@ncu.edu.tw](mailto:jkchang@ncu.edu.tw)

Pores and surface functional groups are endowed on graphene nanosheets (GNSs) to improve their electrochemical Na<sup>+</sup> storage properties. An optimal capacity of 220 mA/g is obtained (at charge–discharge rate of 30 mA g<sup>-1</sup>) in ethylene carbonate/diethyl carbonate mixed electrolyte containing 1 M NaClO<sub>4</sub>. *Ex situ* X-ray photoelectron spectroscopy and synchrotron X-ray diffraction techniques are employed to study the electrode charge storage mechanism. The results indicate that reversible surface redox reactions at electrode surface are predominant for the charge storage in a potential range of 0.5–2.0 V (vs. Na/Na<sup>+</sup>), while Na<sup>+</sup> intercalation/deintercalation between carbon layers occurs at lower potentials. It is found that with increasing the charge–discharge rate by >300-fold (to 10 A g<sup>-1</sup>), a capacity of as high as 85 mAh g<sup>-1</sup> can be retained, reflecting excellent rate capability of our electrode. The physiochemical characteristics that affect the Na<sup>+</sup> storage performance are explored. A highly promising GNS anode for sodium-ion batteries is proposed.

# High Energy Density Electrode Materials Prepared with Metal-Organic Coordination-Polymers for the Applications in LIBs

Jian Chen, Shifeng Yang, Jiao Zhao, Panpan Su, Qihua Yang, Can Li

Dalian National Laboratory of Clean Energy, iChEM, Dalian Institute of Chemical Physics, Chinese Academy of Sciences  
No.457, Zhongshan Road, Dalian 116023, China  
chenjian@dicp.ac.cn

Nanostructured electrode materials can greatly improve the electrochemical performance in LIBs.<sup>1-3</sup> In this work, we developed the metal-organic coordination-polymers as the soft template, and synthesized a series of nanostructured oxides which exhibit outstanding performance in LIBs.

The metal-organic coordination-polymers were synthesized by the soft chemical assembly of metal-ion precursors and organic coordination ligands in the solution. The metal oxides obtained from the metal-organic coordination-polymers usually display almost the same morphology as their precursors. Even the crystal plane orientation could also be inherited from the metal-organic coordination-polymers due to the self-templated nature. Owing to the strong coordination effect, the preparation of metal oxides with the metal-organic coordination-polymer precursors plays a vital role when fabricating metal oxides with multiply metal elements, perfect crystalline and nanostructures.

3,4,9,10-Perylenetetracarboxylic dianhydride (PTCDA) has a rigid and planar molecular structure, which guides its derivatives to inherit a similar lamellar structure. By employing PTCDA as the ligand, we prepared  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  and  $\text{ZnMn}_2\text{O}_4$  nanoplate assemblies inheriting the morphology from the precursors. The nanoplate-stacked  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$  cathode material as shown in Fig. 1 exhibits excellent rate capability and cycling stability, delivering  $120.9 \text{ mAh g}^{-1}$  at a high discharge rate of 40 C and maintaining 84.7% over 500 cycles (Fig. 2). The energy and power density of the material is  $500 \text{ Wh kg}^{-1}$  and  $24 \text{ kW kg}^{-1}$ , respectively, exhibiting a great prospective in application for the power batteries of electric vehicles. The spinel mixed-metal oxides  $\text{MMn}_2\text{O}_4$  ( $\text{M}=\text{Co}, \text{Ni}, \text{Zn}$ ) nanoplate assemblies were prepared by using the similar synthesis route. The prepared  $\text{ZnMn}_2\text{O}_4$  shows the high specific capacity of  $1277 \text{ mAh g}^{-1}$  and good cycling ability when served as the anode materials in LIBs.

By employing the ligand of 1,4,5,8-naphthalenetetracarboxylic dianhydride (NTCDA), the hexagonal nanorings, nanoplates, and nanoparticles of  $\text{Co}_3\text{O}_4$  were derived from the Co-NTCDA coordination-polymers, respectively. When the  $\text{Co}_3\text{O}_4$  hexagonal nanorings (shown in Fig. 3) were served as the anode materials in LIB, they display higher reversible capacity and the improved cycling stability compared with the commercial  $\text{Co}_3\text{O}_4$  nanoparticles. The materials maintain a specific capacity of  $1370 \text{ mAh g}^{-1}$  at the end of the 30<sup>th</sup> charging-discharging cycle (Fig. 4).

Fig.1 SEM images (a)  $\text{NiMn}_3\text{-ptcda}$ ; (b)  $\text{NiMnO}$ ; (c)  $\text{LiNi}_{0.5}\text{Mn}_{1.5}\text{O}_4$ ; (d-e) the corresponding TEM images of (a-c).

\*E-mail: mmorimit@mail.doshisha.ac.jp

Metal/air batteries use oxygen in air as the active mass of the positive electrode (*i.e.*, air electrode) which has theoretically no limitation of the possible discharge capacity, while currently commercialized air batteries are still limited to a primary one and an air secondary battery has not been realized in commercial applications. We have been developing a novel rechargeable air battery consisting of an air electrode, an alkaline electrolyte, and an MH negative electrode, *i.e.*, MH/air secondary battery, which has demonstrated a good cycleability more than 300 charge-discharge cycles and a high energy density over 845 Wh/L [1, 2]. For a further improvement in cell performance, one of the important points is a low polarization air electrode for oxygen reactions during charge and discharge. Especially, a major challenge is to lower the polarization during discharge at a high current density, for which the air electrode is needed to increase the reaction surface area and enhance the gas permeability. The aim of this study is to modify and control the dispersibility of the nano-catalyst on carbon, the conductive supporting material, and to improve the gas diffusion behaviors of the air electrode. We also investigated the performance of the air electrode and the MH/air secondary battery.

The air electrode used graphite powders as a conductive material,  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$  as a bi-functional catalyst, and PTFE as a binder. Graphite powders and oxide catalysts were mixed in two ways; the one is directly mixing them (solid phase mixing) and the other is that they were mixed in ethanol with Triton-X as a dispersing agent (liquid phase mixing). Then, the catalyst loaded graphite powders were mixed with PTFE and paraffin. The PTFE weight ratio was changed up to 30 wt.%. The mixture was rolled and pressed on a nickel mesh, and then the dispersing agent was removed using acetone, followed by heating at 370 °C under nitrogen atmosphere to obtain the air electrode. The polarization behaviors of the air electrode were examined by cyclic voltammetry using a three-electrode cell, in which one side of the air electrode was exposed to air and the other side to 6 mol/L KOH solution.

The results with some modification on the preparation procedure of the air electrode indicated that liquid phase mixing is effective to improve the dispersibility of oxide catalysts on graphite powders compared to solid phase mixing from SEM observation, and the polarization of the air electrode during discharge was small compared to that of our previous study [2]. Especially, the oxygen reduction showed a low polarization at a high current density, while no significant change in the onset potential for oxygen reduction was seen, implying that the overpotential for electron transfer at a low current density is unchanged. In the modification of the preparation procedure, the PTFE ratio was also important on the cathodic polarization of the air electrode; for example, a low weight ratio of PTFE induced a low polarization, which would be due to the enhancement in oxygen permeability in the air electrode. In this paper, we will also present a new method to make the air electrode in which the nano-oxide catalyst is loaded more uniformly and held on graphite powders and the results of the performance of MH/air secondary cells using the graphite-based electrode with nano  $\text{Bi}_2\text{Ir}_2\text{O}_{7-z}$ .

e-mail: jtli@xmu.edu.cn

Si is a promising anode material with a high theoretical specific capacity and a low electrochemical potential of lithiation/delithiation. However, the commercial use of Si-based anodes is still hindered mainly due to the huge volume change in the cycling process, resulting in degradation of the electrode and rapid loss of capacity. The binders are critical to maintain the electrode structure and thereby to achieve repeatable lithium ion battery operation. Different candidates of new binders for Si-based anodes developed up to now include carboxymethyl cellulose (CMC), poly(acrylic acid) (PAA), polyamide imide (PAI), Na alginate (SA).<sup>1,2</sup> In this abstract, a biopolymer, guar gum (GG), has been applied as the new binder for Si anode. Due to the large amounts of polar hydroxyl groups in guar gum molecule (Fig 1a), the robust interaction between guar gum binder and Si nanoparticles is achieved, resulting in a stable Si anode during cycling. More specially, the guar gum binder can effectively transfer lithium ions to the Si surface, which is similar to polyethylene oxide solid electrolyte. The GG binder shows more robust mechanical property with 3.7 times higher viscosity and 1.6 times higher hardness than that of SA binder. At the current density of 2100 mA g<sup>-1</sup>, the Si nanoparticles anode (100 nm) with GG binder delivers a capacity of 2222 mAh g<sup>-1</sup> after 100 charge-discharge cycles, which is much higher than that with SA binder (1377 mAh g<sup>-1</sup>). Our studies for GG binder open a new binder design perspective for Si anodes.

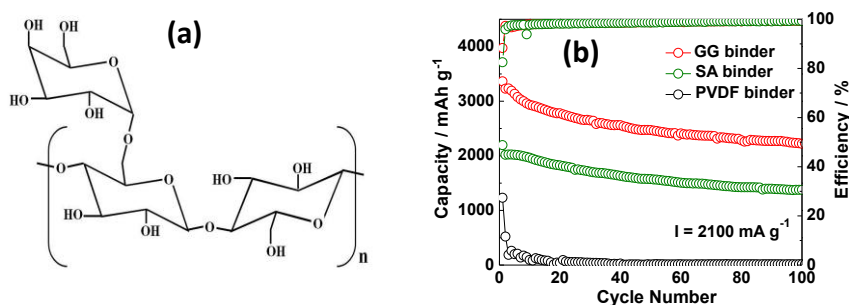

Fig 1 (a) Chemical structures of guar gum, (b) Comparison of electrochemical performance of Si nanoparticles anodes with different binders at 2100 mA g<sup>-1</sup> between 0.01 and 1.2 V, in 1 M LiPF<sub>6</sub>/EC+DMC+DEC (1:1:1, v: v: v) with 2 wt% VC and 10 wt% FEC.

# **In-Situ Electrochemical Analysis for Electrolyte in Vanadium Redox Flow Battery**

Jung Hoon Yang, Jong-Ho Park, Joonmok Shim, Jae-Deok Jeon, Chang-Soo Jin  
*Energy Storage Department, Korea Institute of Energy Research,  
Daejeon 305-343, Republic of Korea  
enviroma@kier.re.kr*

Surge in demand for electrical energy has been a common phenomenon around world. In addition, greenhouse gas emission is another challenge. As a solution to these problems, large-capacity energy storage system have been proposed. Vanadium redox flow battery(VRB) is one of the most viable alternatives. It has two representative advantages:(1) independent design of battery power and capacity and (2) indefinite life of the vanadium electrolytes. However, VRB operation is accompanied by a lot of side reactions including air oxidation of the V(II) ions, hydrogen evolution at the negative electrode, differential transfer of vanadium ions from one half-cell to the other and volumetric transfer of electrolyte from one half-cell to the other. Those side reactions cause the imbalance of capacity in the negative and the positive parts, consequently the loss of operational capacity.

Transfer of the vanadium ions through the membrane can be readily overcome simply by remixing the positive and negative electrolyte because it do not cause the oxidation state imbalance between the positive and negative electrolyte. However, side reactions such as air oxidation and hydrogen evolution can be only corrected by adjusting the oxidation state of the individual half-cell.

Therefore, it is very important to monitor the oxidation state of the individual half-cell and choose the appropriate correction procedures. The open-circuit cell voltage (OCV) is traditionally introduced to indicate the overall cell state of charge(SOC) during the battery operation. This technique employs the Nernst equation to determine the SOC under the assumption that the electrolyte oxidation states are balanced. It cannot give the accurate SOC for the individual half-cell, especially when the oxidation state is imbalanced.

In this study, we suggest a SOC monitoring technique by adapting the in-situ electrochemical analysis cell. By using this cell, we can measure the electrochemical properties of each electrolytes applying cyclic voltammetry, polarization and electrochemical impedance spectroscopy.

# Tuning structure and in situ XRD characterization of Li-rich layered cathode Materials for lithium ion batteries

**ABSTRACT:** The Li-rich layered oxide materials are one of the most promising cathode materials for the next generation of high energy lithium ion batteries due to their high specific capacities, low cost and high safety. Nevertheless, this material has a low coulombic efficiency at the 1<sup>st</sup> cycle, poor rate capability and voltage fade during discharge process. The voltage fade has become a serious problem to keep the Li-rich layered oxide materials from practical use. In order to improve the electrochemical performance of the Li-rich layered oxide materials, in recent years, extensive efforts such as surface coating and preparation of nanoparticles have been devoted to improve the electrochemical performance. However, all those efforts could merely improve the performance to a certain extent. It is well known that the structures of the electrode materials, especially the surface structures are a crucial factor that determines the rate for Li<sup>+</sup> intercalation/de-intercalation. So we have developed Surface structure tuning and solvothermal method of layered metal oxide to prepare this materials, the electrochemical experiment results indicated the as-prepared Li –rich layered oxide materials have excellent rate capacities. In-situ X-ray diffraction (XRD) is a useful technique to monitor the structural changes by real time. With aid of in situ XRD, we captured the information on appearing of the  $\beta$ -MnO<sub>2</sub> phase for the first time, and traced the process of its transformation into layered Li<sub>0.9</sub>MnO<sub>2</sub> in situation through in-situ XRD carefully. It is confirmed that the layered Li<sub>0.9</sub>MnO<sub>2</sub> will transform into spinel phase in subsequent cycles by further TEM results. Our research revealed the key step and mechanism to the “Voltage fade” in Li-rich layered material, which could be instructive and meaningful to inhibit the “Voltage fade” of layered Li-rich materials and improve cycle performances.

Electrospinning technology has been widely utilized to fabricate fibrous gelled polymer electrolyte (FGPE) because it could facilely prepare porous polymer membrane with high porosity and well inter-connective micrometer pores [1, 2]. However, it is because the FGPE has many inter-connective pores in micrometer scale, the absorbed electrolyte might leak out the porous PVdF matrix during cycling resulting in deterioration of battery performances. To retain electrolyte within the fibrous poly(vinylidene fluoride) (PVdF) membranes, poly(methyl methacrylate) (PMMA) was grafted to the electrospun SiO<sub>2</sub>/PVdF nanocomposite fibers via atom transfer radical polymerization (ATRP).

The as-prepared polymer membrane was subsequently activated with the electrolyte 1.0 M LiPF<sub>6</sub> in a mixture of ethylene carbonate/diethylene carbonate (EC/DEC) to form a fibrous gelled polymer electrolyte (FGPE). Effect of grafting degree of PMMA on the morphology, mechanical and electrochemical properties of the fibrous membranes was investigated.

The SiO<sub>2</sub>/PVdF fibrous membrane grafted with 20 wt% PMMA looks like a bat wing (Fig. 1a), the PMMA component surrounds the nanocomposite fibers. It possesses a high ionic conductivity of  $2.31 \times 10^{-3} \text{ S cm}^{-1}$  at room temperature, and a high tensile strength of 8.2 MPa due to integration of the fibers into a coherent whole by the grafted PMMA. The assembled Li/LiFePO<sub>4</sub> cells using this FGPE as separator could deliver 156 and 130 mAh g<sup>-1</sup> at the rates of 0.1 and 2C (Fig. 1b), respectively, and maintain 97% of the initial capacity at 0.1C rate after 90 cycles. The results indicate the FGPE possesses good electrochemical performances and thus is suitable for high-performance lithium-ion batteries.

Fig. 1. SEM image (a) of the fibrous SiO<sub>2</sub>/PVdF-g-PMMA membranes (Scale bar: 5 μm. Inset is the digital photo of a bat.), and its electrochemical properties (b).

Low coulombic efficiency in the first cycle and poor rate capability limit the practical application of Li-rich manganese-based solid solution (LMSS) in high-power lithium-ion batteries [1, 2]. To resolve these problems, a core-shell type of  $Li_{1.2}Mn_{0.54}Co_{0.13}Ni_{0.13}O_2@V_2O_5/C$  (LMSSVC) material was prepared through sol-gel process by using sucrose as carbon source. SEM and TEM images were taken to observe its morphology while XRD pattern was used to determine its crystal structure. Effect of the  $V_2O_5/C$  hybrid shell on the electrochemical properties of the LMSS material was investigated by cyclic voltammetry, electrochemical impedance spectroscopy and galvanostatic charge-discharge measurement.

It can be found that from Fig. 1 (a, b) some  $V_2O_5$  nanoparticles embed evenly in the amorphous carbon matrix was coated on the surface of the LMSS, forming the core-shell morphology.  $V_2O_5$  and carbon components were confirmed to exist in the coating layer by the EDX pattern of the selected area in Fig.1b. The LMSSVC has a porous structure (Fig. 1c), which would not only facilitate good penetration of electrolyte into the interior of bulk particles but also accommodate the volume change of crystals during cycling.

Owing to the Li-host nature of  $V_2O_5$  material and electronic conductivity of carbon, the LMSSVC displays 96% of columbic efficiency in the first cycle at 0.1C rate while the pristine LMSS is 73%. Compared with the LMSS and LMSSV [3], the LMSSVC could deliver the specific capacities of 269, 258, 245, 229, 207 and 176  $\text{mAh g}^{-1}$  at the rates of 0.1C, 0.2C, 0.5C, 1C, 2C and 5C (Fig. 2), respectively, exhibiting a good rate capability. Furthermore, the LMSSVC maintains 92% of the initial capacity at 0.1C rate after 50 cycles, indicating a suitable cycling performance. The results indicate that surface-coating of hybrid  $V_2O_5/C$  layer is an effective method to improve not only the initial columbic efficiency but also the rate capability of the LMSS material.

Fig.1. SEM (a) and TEM (b) images of the LMSSVC and its nitrogen adsorption isotherms and pore size distribution (c) and EDX pattern of the selected area in the TEM image (d).

Fig.2. Rate capabilities of the LMSS, LMSSV and LMSSVC samples in the voltage range of 2.0-4.8V at room temperature.

## Abstract

In recent years,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  (LTO) has being extensively developed as a promising alternative anode material for Li-ion batteries because of its excellent Li-ion intercalation/extraction reversibility and negligible volume change. Moreover, it exhibits a flat discharge platform at 1.55 V (vs. Li) which is higher than the reduction potential of the most organic electrolytes [1], thus avoiding solid electrolyte interphase (SEI) film formation on the surface of LTO particles and ensuring a longer cycling life and better safety of the battery. However, the SEI formation on the LTO surface was found when discharge to 0.01 V [2].

In this study, the electrochemical properties and the SEI formation of electrolyte with different concentrations of butadiene sulfone (BS) on LTO electrodes were studied. According to the results of galvanostatic charge/discharge tests, the LTO electrode charged/discharged in the electrolyte containing 0.5 wt% BS showed the superior electrochemical performance to that in the absence of BS. It was found that the use of BS as an additive can stabilize the SEI film on the LTO surface, and therefore improve the rate capability and electrochemical stability of LTO electrodes. Therefore, the introduction of BS as an additive has promising potential application for improved the electrochemical properties of LTO electrodes especially when discharged to low voltage.

## Abstract

Currently, graphite has been considered as the commonly-used anode material in commercial lithium-ion batteries (LIBs). The low operating voltage of graphite in nature leads to the reduction of lithium metal on its surface ( $\sim 0.2\text{V}$  vs.  $\text{Li}^+/\text{Li}$ ) during discharging, thus possibly affecting the safety of LIBs [1].

In recent years,  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  has been considered as a promising material to replace the graphite as anode material. Since  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  has high operating potential plateau (at  $1.55\text{V}$  vs.  $\text{Li}^+/\text{Li}$ ), the deposition of lithium metal is therefore suppressed. Nevertheless, the electronic conductivity of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  is very poor ( $10^{-13}\text{S cm}^{-1}$ ) and the diffusivity of lithium ion in  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  is also small ( $10^{-8}\text{cm}^2\text{ s}^{-1}$ ), which would limit the electrochemical performance of  $\text{Li}_4\text{Ti}_5\text{O}_{12}$  at high rates [2].

In this study,  $\text{Li}_4\text{Ti}_5\text{Al}_{0.05}\text{O}_{12}/\text{C}$  composite was synthesized via sol-gel method, in which citric acid was used as carbon source and chelating agent. The  $\text{Li}_4\text{Ti}_5\text{Al}_{0.05}\text{O}_{12}/\text{C}$  composite electrode demonstrated superior rate capability to pristine  $\text{Li}_4\text{Ti}_5\text{O}_{12}$ . For instance, its reversible discharge capacity can achieve up to 165, 158, 157, 140 and 118  $\text{mA}\cdot\text{h/g}$  at current density of 1C, 5C, 10C, 20C and 25C, respectively. Moreover, the  $\text{Li}_4\text{Ti}_5\text{Al}_{0.05}\text{O}_{12}/\text{C}$  composite electrode can retain 96% of its initial capacity even after 50 charge/discharge cycles. These results signified that the  $\text{Li}_4\text{Ti}_5\text{Al}_{0.05}\text{O}_{12}/\text{C}$  composite electrode can be considered as one of the promising anode materials for high-performance LIBs.

Lithium-Ion battery has several great performances such as high energy density, no memory effect, low self-discharge and high charge-discharge rate. It is widely used in portable electronics and the storage of alternative energy program. Recently, the development of electric vehicle (EV) is growing; it is necessary to reinforce the safety of battery.

Our research is studying to increase the safety and give maintenance to the electrochemistry properties by using two kinds of STOBAs (Self-Terminated Oligomers Branched Architecture, STOBA). The STOBA is used to add into cathode slurry and prepares an electrode. The cathode particle covers a high ionic conductive oligomer; however, the oligomer will be further polymerized while the battery temperature rises. The battery performance such as safety and electrochemistry properties is observed in high temperature (60 °C). The LLNNO ( $\text{Li}_{1.2}\text{Ni}_{0.2}\text{Mn}_{0.6}\text{O}_2$ ) [1] is a potentially high voltage cathode material and is used in our research. Figure 1 shows the LLNMO half-cells are not affected by the STOBA addition. We believe that the STOBA technology will provide a promising performance in the next generation of lithium ion battery.

Figure 1 The 1<sup>st</sup> cycle charge-discharge result of Lithium-Ion battery which add STOBA in anode or not (blank).

†Correspond to [seungoh@snu.ac.kr](mailto:seungoh@snu.ac.kr)

Lithium-ion batteries (LIBs) have become indispensable parts of modern society due to their high applicability on mobile devices. Carbon-based materials played a significant role in the commercialization of LIBs owing to their long-term stability and cheap prices. However, as applications of power sources increase, the demand for LIBs with higher energy density increases as well. Hence it became necessary to develop alternative electrode materials to overcome the limited capacity of carbonaceous materials. One of the promising candidates is the metal oxide which stores lithium-ion with a conversion reaction. In the conversion reaction, there is no limitation on lithium storage sites since the original framework of oxides is broken along with lithiation. Thus the specific capacity of the material is extremely high compared to graphite or other insertion-type electrode materials. The only factor to limit its capacity is the oxidation states of the transition metal which works as redox center. As shown in Figure 1, there exists a correlation between atomic number of transition metals and the potential of the conversion reaction. This trend is a result of the difference in energy levels of 3d and 4s orbitals which are affected by the number of protons in the nucleus. Since it is hard to reduce titanium and vanadium to their elemental states, there have been no reports on conversion-type lithium storage in those metals. However, it can be inferred from the regression curve that there could be vanadium oxides which show conversion-type lithium storage around 0 V (vs.  $\text{Li/Li}^+$ ).

**Figure 1. The empirical values and their regression curve of conversion plateau of 3d transition metal oxides[1].**

In this work, we propose lithium metavanadate ( $\text{LiVO}_3$ ) as a novel conversion-type negative electrode.  $\text{LiVO}_3$  provides reversible capacity over  $1,000 \text{ mAh g}^{-1}$ , which is much higher than other vanadium oxides, with long plateau around 0 V (vs.  $\text{Li/Li}^+$ ). Electrochemical techniques such as PITT and GITT were mainly used to elucidate the lithium storage mechanism of the material. Moreover, various tools including synchrotron X-ray spectroscopy and ab-initio quantum calculation were also employed to obtain more detailed information on the structure change during lithiation.

# Structural Effects of Spinel $\text{LiMn}_{1.5}\text{Ni}_{0.5}\text{O}_4$ on Their Electrochemical Properties

Josh Y. Z. Chiou, Shou-Huang Su, She-huang Wu\*  
Department of Materials Engineering, Tatung University  
40 Chungshan N. Rd., Sec. 3, Taipei 104, Taiwan  
e-mail: [shwu@ttu.edu.tw](mailto:shwu@ttu.edu.tw)

$\text{LiMn}_{1.5}\text{Ni}_{0.5}\text{O}_4$  (LNMO) samples were synthesized via a spray combustion method followed by heat treatment at temperature of 900°C for 12 hours (LNMO900) and post annealing at 700°C under air for various durations (0 to 96 hours), shown as LNMO700- $X$ , where  $X = 0 \sim 96$  ). Moreover, sample heated at 900°C for 12 hours followed by quenching in liquid nitrogen (LNMO900Q) and sample calcined under oxygen atmosphere instead of air (LNMO900O) were also prepared. The crystalline structures and amounts of secondary phases were studied by X-ray powder diffraction (XRD). Slight shifting of the (111) reflection peak of spinel to lower angle and lowering the intensity of the rock-salt phase ( $\text{Ni}_x\text{O}$  or  $\text{Li}_x\text{Ni}_{1-x}\text{O}$  or  $\text{Li}_x\text{Ni}_y\text{Mn}_z\text{O}$ ) upon increasing the annealing time were observed as reported previously [1]. The appearance of the peaks in addition to those of the LNMO900 sample in the 700°C annealed samples, that manifests the existence of order ( $P4_332$ ) phase in the annealed LNMO samples. Neutron powder diffraction (NPD) with Reitveld refinement was employed to investigate the phase fractions of the ordered, disordered  $Fd\bar{3}m$ , and rock-salt  $\text{Li}_x\text{Ni}_{1-x}\text{O}$  the prepared samples. The morphology and particle size of samples were analyzed by Scanning Electron Microscopy (SEM). It was found that similar particle size of 1-1.5  $\mu\text{m}$  is determined independent of annealing process. From the results of the capacity retention study for the prepared samples, LNMO900 shows the best cycling performance among the prepared samples. The reasons of these results will be revealed from the studies of cyclic voltammetry at various scan rates and electrochemical impedance spectroscopy of the coin-cells prepared with the prepared samples in company with the dissolution test of transition  $\text{Mn}^{2+}$  and  $\text{Ni}^{2+}$  into electrolyte with/without cycling. The relationship between the crystalline structure and the cycling performance of LNMO will be understood in the near future.

Carbon nanohorns (CNHs) consist of horn-like tubes approx. 3–25 nm in diameter and 20–150 nm in length, which are closed at one end with a cone. The single-wall CNHs generally occur as an aggregate with a particle size ranging from 100 nm to several  $\mu\text{m}$ . Similar to graphenes and carbon nanotubes, CNHs also demonstrate good electrical and thermal conductivity, as well as high mechanical stability and high specific surface area. They are generally produced by laser ablation of pure graphite with high production rate and high yield, and typically form radial aggregates. In this paper, we prepared turpentine oil derived CNHs using nebulized spray pyrolysis technique and report on the electrochemical performances of such nano carbon structures. The structure and morphology of the resulting nano carbons were investigated with X-ray powder diffraction (XRD), Raman spectroscopy, Scanning Electron Microscope (SEM) and Transmission Electron Microscope (TEM). Cyclic voltammetry (CV) and cyclic test of the CNHs as an anode material for lithium ion batteries were also studied. The CNHs show a high specific capacity in the first cycle and high capacity retention until the 50<sup>th</sup> cycle at a constant current density of 100 mA/g, showing its potential use as an anode material in lithium-ion batteries. Those electrochemical characteristics were a result of the unique nanostructure and high conductivity of CNHs.

# Low-Temperature Operation Performance of LiFSI-Based Low EC Content Electrolyte with Specific Solvation State

Satoshi Uchida, Masaki Yamagata and Masashi Ishikawa

Department of Chemistry and Materials Engineering, Faculty of Chemistry, Materials and Bioengineering, Kansai University, 3-3-35 Yamate-cho, Suita 564-8680, Japan  
masaishi@kansai-u.ac.jp

The conventional electrolytes for Li-ion batteries are composed of  $\text{LiPF}_6$  or  $\text{LiBF}_4$  salts and mixed solvents of ethylene carbonate (EC) with a high dielectric constant and linear carbonates with low viscosity. The conventional electrolytes contain 30 – 50 vol.% EC to obtain high ionic conductivity by sufficient dissociation of Li salts. However, since EC has high melting point ( $38^\circ\text{C}$ ), the conventional electrolytes are not suitable for low-temperature ( $\leq -20^\circ\text{C}$ ) operation of Li-ion batteries. To achieve excellent low-temperature operation performance, the EC content should be reduced. On the other hand, reduction of EC content leads to decrease of ionic conductivity of electrolytes and generally degrade room-temperature rate performance of Li-ion batteries.

Previously, we found that lithium bis(fluorosulfonyl)imide (LiFSI) shows good ionic conductivity in a low EC content mixed solvent by very weak interaction between  $\text{Li}^+$  and FSI $^-$ . In addition, we also reported that the LiFSI-based low EC content (10 vol.%) electrolyte has specific dissolution process and shows outstanding room temperature rate performance than the conventional electrolytes.<sup>1)</sup> This result indicates that our electrolyte has possibility of achieving both excellent low-temperature operation performance and room-temperature rate performance. Therefore, we optimize the solvents composition of our electrolyte for above objective and evaluate its low-temperature operation performance in this work.

1.0 or 2.0  $\text{mol dm}^{-3}$  LiFSI dissolved in mixed solvents of EC, dimethyl carbonate (DMC) and ethylmethyl carbonate (EMC) (1:4.5:4.5 v/v/v) was used as the electrolyte with low EC content (denoted by 1.0 or 2.0  $\text{mol dm}^{-3}$  LiFSI/EC:DMC:EMC = 1:4.5:4.5 v/v/v), while 1.0  $\text{mol dm}^{-3}$   $\text{LiPF}_6$ /EC:EMC = 1:1 v/v were used as reference conventional electrolyte. Graphite or  $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$  (NMC) composites containing conductive additive and binder were used as negative and positive electrodes, respectively. The respective mass of active materials in the negative and positive electrodes were ca. 4.5 and 9.5  $\text{mg cm}^{-2}$ . We assembled graphite/NMC cells with each electrolyte and evaluated their battery performances.

Fig. 1 shows room-temperature charge-discharge rate performances of graphite/NMC cells containing each electrolyte ( $1\text{C} = 160 \text{ mA g}^{-1}$ ). Our low EC content electrolytes shows better rate performance than reference conventional electrolyte. It should be noted that 2.0  $\text{mol dm}^{-3}$  LiFSI system shows superior rate performance even though the ionic conductivity of low EC content system decreases with increasing concentration of LiFSI. This result indicate that the room-temperature rate performance of our low EC content system is dominated specific dissolution process that was previously reported<sup>1)</sup> rather than bulk ionic conductivity. Fig. 2 shows charge-discharge curves ( $1\text{C}$ ) measured at  $-20^\circ\text{C}$  of graphite/NMC cells containing each electrolyte. In low-temperature operation, 1.0  $\text{mol dm}^{-3}$  LiFSI system shows best performance. Although low-temperature operation performance was sensitive to increase in bulk viscosity, 2.0  $\text{mol dm}^{-3}$  LiFSI system shows far superior low-temperature operation performance than reference conventional electrolyte.

2. Jülich Aachen Research Alliance: JARA-Energy

All-solid-state Li battery containing oxide-class solid electrolyte is considered to be out stand from their high safety and higher energy density. Compared to the other class the solid Li ionic conductors, oxide-class Li ion conductors have additional advantages of easier material handling during synthesis, higher chemical stability and wider electrochemical window. The use of LLZ as solid electrolyte for solid-state battery had been reported in several papers. However, the reported solid-state batteries were all constructed with a thin film cathode which was made either by physical vapor or sol-gel deposition[1-2]. The thin film cathodes were usually under or around 1  $\mu\text{m}$  in thickness which made the energy density of these batteries not practical.

In order to realize the using of oxide-class Li ion conductor as solid electrolyte for a Li battery, Ta-substituted  $\text{Li}_7\text{La}_3\text{Zr}_2\text{O}_{12}$  (LLZ:Ta) powder had been synthesized via solid state reaction. LLZ:Ta with an optimized sintering parameter exhibits a high Li ion conductivity of  $7.8 \times 10^{-4} \text{ S cm}^{-1}$  at 30 °C with a relative density of ~94%. The material was further implanted as a solid electrolyte by using screen printing to put on thick  $\text{LiCoO}_2$  (> 50  $\mu\text{m}$ ) as cathode. A proper sintering process was invested for well bonding the thick cathode layer to the supporting electrolyte. The constructed all-solid-state Li batteries exhibited good charge-discharge utilization of active material of more than 80% which is equal to a capacity density of  $\sim 0.9 \text{ mAh cm}^{-2}$  at 100 °C. It also exhibited good cycle ability that one hundred of cycles were achieved at temperature of 50 °C. Thus, LLZ:Ta shows as a promising candidate for all-solid-state Li battery. However, the reduction of high internal resistance of the cell is still the major challenge for further improvement of the battery performance, especially if the application of this all solid state Li battery is toward room temperature. During this presentation, results from material chemical stability, cell morphology, electrochemical performance and the challenges of building up Li battery by using LLZ:Ta will be discussed.

*dwkim1@korea.ac.kr*

It is of great significance to improve the power density of Li ion batteries in pursuit of high-end products and technologies. Various nanoscale structures including nanoparticles, nanowires, nanosheets, and nanotubes have been designed for high-efficiency energy applications. In particular, electrodes for Li-ion batteries with a long cycle life, high energy, and high power rate capability can be associated with three-dimensional (3-D) nanoarchitectures. There are two types of 3-D nanoarchitectures: self-supported nanoelectrode materials and nanoarchitected current collectors. Self-supported nanoelectrode materials have direct electronic pathways, allowing for efficient charge transport and the accommodation of the volume expansion during  $\text{Li}^+$  insertion/removal cycling. Herein, we fabricated two types of 3-D nanoarchitected current collectors consisting of 1-D Cu/C core/sheath nanowires and 2-D Cu/C core/sheath nanonets. High-capacity Ge nanoarrays were deposited onto the as-prepared Cu/C nanowires or Cu/C nanonets via thermal evaporation and a  $\text{GeO}_2$  removal process. The obtained samples have advantages over Li-ion battery anodes because of the highly porous ordered and aligned nanostructures. The Cu/C nanonet-based Ge anodes exhibited a large reversible capacity of  $933 \text{ mA h g}^{-1}$  at a rate of 1 C over 1000 cycles and an excellent rate capability of  $1017 \text{ mA h g}^{-1}$  at a rate of 10 C over 200 cycles. More importantly, as the Ge nanoarrays mass loading increased, the areal capacity can be successfully enhanced to  $2.4 \text{ mA h cm}^{-2}$ . Our strategy on the 3-D nanoarchitected electrodes has significant advantages such as a long cycle life and high-rate capabilities for the anode design of Li-ion batteries and also allows for their potential application to other applications, such as supercapacitors, solar cells, and so on.

# **The Effects of Substrates on the Phase Formation Behavior and the Electrochemical Properties of $\text{Li}_2\text{MnSiO}_4$ Cathode Thin Films Deposited by RF Sputtering for Thin Film Batteries**

Lithium ion batteries have been widely used in mobile electronics applications by virtue of their high energy density. Recently, the solid-state thin film batteries have received growing attention because of their on-board capability with microelectronic circuits such as microelectromechanical systems and smart cards [1]. They consist of a cathode, electrolyte, and an anode. Among them, the thin film cathode plays a key role in the aspect of providing high capacity, thus the selection of the material and its properties in thin film form are important. Various kinds of cathode materials have been developed in bulk form [2]. Among them,  $\text{Li}_2\text{MnSiO}_4$  has been considered as an attractive cathode material due to its potential high capacity, being expected to use more than one Li ion per formula unit because of its two redox couples,  $\text{Mn}^{2+}/\text{Mn}^{3+}$  and  $\text{Mn}^{3+}/\text{Mn}^{4+}$  [3]. Its theoretical capacity is 333 mAh/g.

In this research,  $\text{Li}_2\text{MnSiO}_4$  thin films were deposited on various substrates by rf sputtering method. The substrates were Al foil, SUS and Ni ones which were electrically conductive for being used as current collectors. Powder-type  $\text{Li}_2\text{MnSiO}_4$  sputtering targets with and without carbon were prepared by solid-state reaction using planetary ball-mill. As-deposited thin films were amorphous, thus for some samples, post-annealing was applied in order to crystallize the films. Oxygen should be prevented during both the deposition and annealing processes in order to suppress the oxidation of  $\text{Mn}^{2+}$  of the  $\text{Li}_2\text{MnSiO}_4$  phase. It was revealed that the formation of  $\text{Li}_2\text{MnSiO}_4$  phase was favorable on the SUS substrates. The electrochemical performances of both crystallized and amorphous  $\text{Li}_2\text{MnSiO}_4$  thin films were evaluated with liquid electrolyte in coin cells. The capacities of  $\text{Li}_2\text{MnSiO}_4$  cathode thin films with carbon were higher than those without carbon. Improved cycling properties of the  $\text{Li}_2\text{MnSiO}_4$  cathode thin films were appeared.

## Abstract

The LiFePO<sub>4</sub>/C (LFP/C) was synthesized by a solid-state ball-milled method; LATP solid electrolyte was prepared by a sol-gel method. The surface-modified LiFePO<sub>4</sub>/C composite cathode materials was co-coated with both in-situ graphene and Li<sub>1.4</sub>Al<sub>0.4</sub>Ti<sub>1.6</sub>(PO<sub>4</sub>)<sub>3</sub> (LATP) solid-state electrolyte via a one-pot sol-gel process. The surface-modified LiFePO<sub>4</sub>/C cathode materials were examined by XRD, SEM/EDX, TEM, micro-Raman spectroscopy, EA, and XRF. The 2032 coin half-cell was assembled to examine the electrochemical performance of the surface-modified LiFePO<sub>4</sub>/C cathode materials. The galvanostatic charge-discharge test was conducted in the potential range of 2 - 4.0 V using LiPF<sub>6</sub> + EC: DEC (1:1, v/v) electrolyte at various C-rates (0.1C-10C) at 25°C, 55°C and -20°C. It was revealed that the capacities retention of the bare LFP/C and the surface-modified LFP/C cathode materials at 1C/1C for 200 cycles are 89.53% and 91.28%, respectively, at 25°C. Moreover, we also found that the capacities retention of the bare LFP/C and the surface-modified LFP/C cathode materials at 1C/1C for 200 cycles are 58.7% and 86.2%, respectively, at 55°C. At -20°C, the discharge capacity of the surface-modified LFP/C cathode materials is around 100 mA g<sup>-1</sup>; in comparison, only 60-70 mAh g<sup>-1</sup> for bare LFP/C material. According to the results, we found that the as-prepared GNS+LATP co-coated LFP/C materials exhibit excellent electrochemical performance. It can be a promising candidate cathode material for the rechargeable lithium ion battery.

# Characterization of sodium based ternary polymer electrolytes

Andrea Boschin and Patrik Johansson  
Chalmers University of Technology,  
SE - 412 96 Göteborg, SWEDEN  
andrea.boschin@chalmers.se

At present sodium ion batteries (SIBs) represent a possibly cheaper and more sustainable alternative to lithium ion batteries [1]. Indeed, while sodium shows similar chemical and electrochemical properties to lithium, paving the way for fast development, the resources of sodium are in principle unlimited. The SIB electrolyte research is diverse; organic solvents, polymers, and ionic liquids are all being used as matrices [1-3]. Ion conducting solid polymer electrolytes (SPEs) avoid the usage of organic solvents and can thereby enable fabrication of flexible, safe and compact solid-state structures. The ionic conductivities of sodium and lithium SPEs, based on poly (ethylene oxide) (PEO) are comparable [4-6], however, both having rather low conductivity values: ( $10^{-7}$ - $10^{-5}$ )  $\text{Scm}^{-1}$  at room temperature.

The main part of the research performed so far on  $\text{Na}^+$  conducting SPEs was carried out during the 1990's [5-6]. Recently [7], we have characterized the binary SPE systems NaTFSI-PEO and NaFSI-PEO, where basically the TFSI anion acts inhibiting on crystallization, as previously shown for the corresponding Li-based SPEs [8], while the FSI anion, despite being chemically very similar, seems to favor it – in these often semi-crystalline systems. The highest ionic conductivity at 20°C was obtained for NaTFSI(PEO)<sub>9</sub>.

In order to further improve the ionic conductivity without compromising safety [9], different amounts of N-propyl-N-methyl-pyrrolidinium (PYR<sub>13</sub>) based ionic liquids (ILs) with the very same anions (FSI, TFSI) have here been added; creating ternary polymer electrolytes NaX-PEO-PYR<sub>13</sub>X. The resulting ternary systems are compared with the analogous binary systems in terms of basic physico-chemical properties obtained by dielectric spectroscopy, differential scanning calorimetry, and Raman spectroscopy. Overall, the addition of ILs to the binary systems increases their conductivity and the PEO chain mobility. These effects are most likely due to the presence of the PYR<sub>13</sub> cation, which does not interact strongly with the PEO chains, and the contribution of the different ions is crucial in view of application of ternary systems in SIBs.

**Figure 1:** Ionic conductivities of the NaFSI(PEO)<sub>9</sub>-PYR<sub>13</sub>FSI system.

Among various metal-air batteries, the rechargeable zinc-air battery has been considered to be an attractive choice because of its unique benefits, such as low cost, safety, and environment friendliness [1]. However, there are still many challenges to overcome, such as inherent sluggish kinetics of the oxygen reduction reaction (ORR) and oxygen evolution reaction (OER) and high overpotential [2]. It has been reported that transition metal oxides are the most promising bifunctional electrocatalysts in alkaline solution [3]. The substitution of nickel by iron in spinel  $\text{NiCo}_2\text{O}_4$  was found to enhance oxygen evolution in the alkaline media [4]. Here, we employ an iron-doped  $\text{NiCo}_2\text{O}_4$  spinel structure supported on carbon black as an efficient bifunctional electrocatalyst for both the ORR and OER. The hybrid electrocatalyst is facilely synthesized via hydroxide precipitation and thermal treatment. The carbon black induced into the iron-doped  $\text{NiCo}_2\text{O}_4$  reduces the overpotential and markedly promotes the currents of the ORR and OER in alkaline electrolytes. The activity of  $\text{Fe}_x\text{Ni}_{1-x}\text{Co}_2\text{O}_4$ /carbon black composites is much higher than that of their corresponding oxides for both the ORR and OER. Furthermore, the rechargeable zinc-air battery with the optimized  $\text{Fe}_x\text{Ni}_{1-x}\text{Co}_2\text{O}_4$ /carbon black composite as a bifunctional electrocatalyst displays a high activity and good stability during a full cell charge-discharge process.

Fig. 1. The repeated charge-discharge curves of a Zn-air battery with a  $\text{Fe}_x\text{Ni}_{1-x}\text{Co}_2\text{O}_4$ /carbon black composite working as the air cathode during discharging and the oxygen evolution anode during charging.

# A comparative study on $\text{Li}^+$ ion migration characteristics in the interphases of positive and negative electrodes

Tae-jin Lee, Taeho Yoon, Jiwon Jung, Jiyong Soon, Jae Gil Lee, Ji Heon Ryu<sup>1</sup>, and Seung M. Oh\*

Department of Chemical and Biological Engineering, Seoul National University, 1 Gwanak-ro, Gwanak-gu, Seoul 151-742, South Korea

Lithium-ion batteries, beyond the traditional IT mobile devices, has attracted to be applied to EV and ESS. It is required higher energy density to meet these expectations. It would be one method for 5V class positive electrodes to be applied, they have not been commercialized due to their operation voltage beyond the stable electrochemical stability windows of electrolytes[1]. The commonly used electrolytes are decomposed and surface film deposit on these high voltage positive electrodes[2].

Film is the interphase between electrolytes and positive electrodes. Because it is  $\text{Li}^+$  migration path in solid, more sluggish than liquid electrolytes, it determines the kinetics and the reversibility of positive electrodes[3]. Studies on these phenomena have been mainly performed for SEI on negative electrodes[4, 5]. But, it has not been paid attention about the characteristics of  $\text{Li}^+$  migration in the film deposited on positive electrodes. So, this study is necessary more than anything else to improve properties of interphase on positive electrodes.

In this study, the  $\text{Li}^+$  ion conductivity of film is analyzed by some comparative studies with SEI on negative electrodes, which has been mainly studied. At first, it needs to be calibrated about the quantities of the decomposed electrolytes or thickness of interphase between them prior to the analysis of their ion conductivity. In cyclic voltammetry of only electrolyte system, anodic current is much lower than cathodic current.(Fig. 1. (a), (b)) This means indirectly film is much thinner than the SEI. Nevertheless, EIS shows that film resistance is much larger than SEI(Fig. 2.(a), (b)), it means that ion conductivity of film is inferior compared to SEI. This implies that components of these two interphases are different from each other. So, the ultimate goal of this study is to find out the different mechanism of  $\text{Li}^+$  migration in film on positive electrodes compared to SEI on negative electrodes.

Lithium-rich layered cathode material is now considered as a promising cathode material candidate due to its high energy density. This type of cathode material, however, has severe drawbacks of a rapid capacity fading arising from charge/discharge cycle repetitions and a low electron conductivity leading to capacity decrease at high current density. To overcome such problems, additional modifications (e.g., those where cathode materials are coated with other stable one to protect from undesired side-reaction) [1, 2] and additional treatments (e.g., those where they are adopted to maximally promote the potential properties of the material) have been majorly proposed [3, 4], but there is still a room for innovation to arrange structural and morphological feature of the material itself. Our group have recently reported the good cycle stability and the high rate capability of a  $\text{Li}_{1.2}\text{Ni}_{0.18}\text{Mn}_{0.59}\text{Co}_{0.03}\text{O}_2$  cathode material modified with  $\text{LiCoPO}_4$  nanoparticles [5]. We herein present a unique strategy to obtain size-regulated precursor fine particles, whose morphology was also controlled to have a microscopic homogeneity based on a reverse microemulsion technique (Fig. 1A). The cathode material with the same composition of  $\text{Li}_{1.2}\text{Ni}_{0.18}\text{Mn}_{0.59}\text{Co}_{0.03}\text{O}_2$  was synthesized from such precursor particles in order to look at the impact of such a precursor synthesis on the eventual cell performances of the material (Fig. 1B). The resulting material demonstrated a good cycle stability (50th cycle discharge capacity: 281 mAh/g at 20 mA/g) without any additional modifications or treatments and a high capacity retention (52%) even at 640 mA/g (Fig. 2A). According to the impedance spectra of an electrode made from the cathode material, the overall features of the small semicircle observed in the high frequency after charging (Fig. 2B, inset) are almost identical regardless of the cycle number. This is a good indicator demonstrating that for the particles of the cathode material, a coherent smart solid-electrolyte-interface (SEI) layer may be formed on the surface of the particles whereby they are protected from any undesirable side-reactions during the following cycles after the 1st cycling. In addition, this experimental fact strongly supports the result shown in Fig. 2A exhibiting that the cathode material has the potential ability to yield a long-term smooth  $\text{Li}^+$  diffusion even under high-rate conditions.

It is well known that graphite negative electrode, which represents the preferred anode material in LIBs, delivers poor electrochemical performance in low temperature condition. The reduced ability of graphite at low temperature has been attributed to several factors; ion mobility in the electrolyte, transport properties of passivation films, increased charge transfer resistance and reduced solid state ion diffusivity within graphene sheets. In the past decades, several approaches have been pursued to overcome these limitations.

In this work, our prime concern is to access the low temperature characteristic of surface film derived from elemental sulfur additive, and further understand the how chemical composition of SEI has an effect on the low temperature performance of graphite. To this purpose, a comparative study is made on the surface films derived from the sulfur-added and sulfur-free electrode, from which the performance at low temperature, the resistances and chemical composition of sulfur-derived surface film are addressed. Electrochemical impedance spectroscopy (EIS) is utilized to study the resistance of electrodes and to evaluate its dependence on temperature, whereas X-ray photoelectron spectroscopy (XPS) is used to analyze the film composition of surface films.

Compared to the sulfur-free electrode, adding 0.5% sulfur showed good performance at low temperature condition. SEI film with sulfur compounds is less resistive at low temperature, especially in the charge transfer step. The elemental sulfur is reduced at the 1st lithiation step, producing long chain polysulfide which readily reacts with carbonate electrolytes (EC, EMC, and DEC) [1]. As a result, generated thiocarbonates make sulfur-containing SEI composed of  $\text{Li}_2\text{S}$ , C-S-C, and  $-\text{CO}_2\text{S}-$  on the graphite electrode. Finally, we propose the mechanism of SEI formation with elemental sulfur additive through a reaction between carbonate electrolyte and long chain polysulfide, and the relation between SEI composition and charge transfer barrier.

**Fig. 1. Proposed mechanism of the film forming process with elemental sulfur additive in graphite negative electrode.**

# A Renaissance for Solid Polymer Electrolyte through Alternative Host Materials: Polycarbonates

Daniel Brandell, Bing Sun, Jonas Mindemark  
Department of Chemistry – Ångström Laboratory, Uppsala University  
Box 538, 751 21 Uppsala, Sweden  
Daniel.Brandell@kemi.uu.se

Solid polymer electrolytes (SPEs) have since their discovery in the 1970s been considered a promising class of materials for different electrochemical applications due to their mechanical flexibility, chemical and electrochemical stability, non-toxicity and the safety of the resulting devices – not least for rechargeable Li-batteries. SPEs have, however, not yet been realized to any great extent due to several shortcomings, primarily their inherent low ionic conductivity. This is likely associated to the rather limited number of polymer host materials which have been explored by the research community: the overwhelming majority of relevant publications and patents have been on poly(ethylene oxide) (PEO) materials. PEO displays some appealing properties such as low  $T_g$  and a good dissolution of many Li-salts, but are also associated with problems: semi-crystallinity, low cation transference numbers, and temperature sensitivity. Despite intense research on this category of materials during several decades, where the inclusion of inorganic nanoparticles have constituted the perhaps most promising strategy for achieving higher ionic conductivities, the conductivity values have not yet reached the levels which are considered necessary for most commercial applications ( $10^{-2}$ - $10^{-3}$  S/cm) without the inclusion of a significant part of liquid components.

The rapidly expanding market for electric vehicles (EVs) demand batteries with higher energy density, improved safety, and prolonged lifetime. These criteria are largely met by SPEs, and the research field could therefore experience a true renaissance if some of the inherent problems for this class of materials are properly solved. Alternative polymer materials to PEO could then provide a route forward and bring SPEs further towards implementation in commercial devices.

In this context, we have been targeting polycarbonates – specifically, poly(trimethylene carbonate) (PTMC) – for Li- and Li-ion batteries. PTMC has a somewhat higher  $T_g$  than PEO, but is amorphous and display better mechanical integrity, not least at higher temperatures. The  $\text{Li}^+$  transference numbers are also much higher than for PEO. We have recently shown that functional Li-batteries can be constructed using PTMC as an electrolyte host material for LiTFSI salt [1]. We have also shown that the ion transport and/or mechanical properties can be improved by lowering the  $T_g$  through monomer functionalization, cross-linking [2] or through co-polymerization with polyesters [3]. Moreover, we have been able to significantly improve the device performance by tailoring the battery fabrication procedure using oligomer components [4] and utilized X-ray Photoelectron Spectroscopy (XPS) to better understand the interfacial chemistry between the SPE and common Li-battery electrode materials [5].

In this current presentation, we will discuss in-depth studies of the ionic transport properties in the PTMC-materials investigated by an interplay of computational (Molecular Dynamics) and experimental techniques (NMR, impedance spectroscopy, FTIR), and highlight some key characteristics in comparison with PEO-based SPE counterparts. The differences regarding polymer-ion interactions present novel insights for strategies to improve the transport properties of SPEs. We will also discuss PTMC-based SPEs which are operational in Li-battery cells at ambient temperatures, without any addition of liquid components.

# Electrochemical behaviour of tin(IV) oxide electrodes in lithium-ion batteries at high potentials

Solveig Böhme, Kristina Edström, Leif Nyholm  
Department of Chemistry – Ångström Laboratory  
Uppsala University  
Box 538, 751 21 Uppsala, SWEDEN  
solveig.bohme@kemi.uu.se

In commercial lithium-ion batteries graphite is currently the most common anode material. However, graphite has a rather limited volumetric and gravimetric capacity which is a drawback when higher energy densities are required, for instance, in cars. Here, other materials with higher capacities and energy densities like the alloying materials tin and silicon are, hence, required. Even bigger capacities could be obtained using tin oxide based compounds due to a combination of the tin oxide conversion reaction converting lithium to tin and lithium oxide and the alloying reaction between tin and lithium. However, tin oxides usually suffer a great capacity loss after the first cycle due to the irreversibility of the tin oxide reduction.<sup>[1,2]</sup> Nevertheless, there have been some reports suggesting a limited reversibility of the tin(IV) oxide conversion.<sup>[3-6]</sup>

In this work we have investigated the voltammetric behaviour of tin(IV) oxide electrodes within different potential windows in order to study the influence of the alloying reaction on the conversion reaction (excluding the alloying reaction by cycling to 0.9 V vs.  $\text{Li}^+/\text{Li}$ ). In addition, rather high voltages (up to 3.7 V vs.  $\text{Li}^+/\text{Li}$ ) were applied to check the tin(IV) oxide conversion reversibility as well as electrode and electrolyte stability under these conditions. The results were also compared with those presented in an earlier model study carried with our group.<sup>[6]</sup> Cycling experiments were likewise carried out at 60°C and these results will be compared to those obtained for cycling at room temperature. The products formed at different potentials and temperatures were investigated using XPS and SEM. The results confirmed the presence of a partial reversibility of the tin(IV) oxide conversion reaction which was enhanced at 60°C. It will be demonstrated that cycling at a higher temperature lead to larger capacities of tin(IV) oxide electrodes. In addition, the influence of different cycling rates on the capacity will be discussed.

# Capacity enhancement of semi-solid flow capacitor using quinonic compounds

H. Saito, D. Komatsu, T. Tomai, I. Honma

*Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, Japan*

*2-1-1, katahira, Aoba-ku, Sendai, Miyagi, Japan*

*hayate@mail.tagen.tohoku.ac.jp*

For grid-scale energy storage, the semi-solid flow cell, consisting of an electrochemical charge-discharge cell connected to an external circulatory system of pumps and reservoirs, has been developed. Among the flow cells, semi-solid flow capacitor (SFC) stores electrical charge in an electrical double layer at the carbon-electrolyte interface in a flowable carbon-electrolyte suspension (slurry), so the SFC exhibits higher power density than semi-solid flow battery<sup>[1]</sup>. However, compared to the battery system, SFC slurry has limited energy density.

Our previous study revealed that the fixed capacitor using the nanoporous carbon holding organic compounds exhibited high energy density ( $>20 \text{ Wh kg}^{-1}$ ) and high power density ( $>5 \text{ A g}^{-1}$ ) without the degradation after 10000 charge/discharge cycles<sup>[2]</sup>. To address the limitation of the energy density (capacity) of SFC slurry, in this study, we enhanced the capacity of the slurry by using redox-active organic compounds (Fig. 1). We applied the nanoporous carbon holding quinonic/hydroquinonic compounds to carbon-electrolyte suspension (quinonic/hydroquinonic slurry) for flowable electrodes in the SFC.

The flowable quinonic/hydroquinonic slurry electrode was prepared by dispersing the organic compound-carbon composite in 0.5 M  $\text{H}_2\text{SO}_4$  aqueous solution. We employed tetrachlorohydroquinone (TCHQ) as cathode active material and anthraquinone (AQ) as anode active material in positive and negative slurry electrodes, respectively. The weight ratio of the organic compound-carbon composite to 0.5 M  $\text{H}_2\text{SO}_4$  aqueous solution was fixed at 13 : 87. The flowability of the slurry was maintained in the range less than this weight ratio. Fig. 2 shows the potential profiles of the positive and negative slurry electrodes. By using the redox reactions of quinonic/hydroquinonic compounds in positive and negative slurry electrodes, we achieved the enhancement of the capacity of the slurry for SFC.

Recently, reduced graphene oxide (rGO) have been considered as an attractive material due to its intrinsic characteristics such as physical, mechanical and electrical properties since the discovery of its freestanding form in 2004 [1]. Due to its superior electrical conductivity and high theoretical surface area, rGO has been considered favorably as a promising material for secondary batteries such lithium-ion battery anodes [2].

In this study, rGO is used to a carbon black into Si/C anode electrode in order to enhance the capacity and electrochemical reversibility. According to the research [3], the carbon-oxygen functional groups on rGO are able to fabricate ionic host SEI, which improves the performance of lithium-ion battery including reversible capacity and cycle ability.  $\text{Li}^+$ , MI, and  $\text{H}_2\text{O}$  are fabricated to form a unique ionic host SEI on the rGO's surface duo to the higher reduction potential of the combined reaction.

Figure 1 shows three kinds of electrolyte additives (MI,  $\text{H}_2\text{O}$ , MI/ $\text{H}_2\text{O}$ ) has been added compares with the blank electrolyte. The electrolyte contains MI/ $\text{H}_2\text{O}$  demonstrates better performance via others. This result demonstrates that the ionic host SEI is able to fully functionalize in battery system in which promotes application of lithium-ion rechargeable batteries.

araij@yamaha-motor.co.jp

Lithium ion batteries (LIBs) are widely used as power sources in electric vehicles, which include such as power-assisted bicycles (e-bikes), electric assisted wheel-chairs, and electric scooters, as a power source. In commercial products, there is a need for a stable power supply; it is of important in commercial products, however, LIBs lose their energy and power during charge-discharge cycles and during storage. To design and develop reliable products, it is necessary to understand and control the lifespan of LIBs's life. There have been many attempts to extensive efforts focused on the development of battery-life models to analysis analyze the degradation of LIBs's degradation. [1] Among them, the differential voltage analysis method is a useful technique to investigate the reason for the capacity loss in LIBs. [2] The in one study, it was shown showed that the reduction in battery capacity fade was due to the loss of positive/negative capacity balance caused by resulting from the side reactions at the negative electrode. However, this method cannot provide the information regarding the interior inside of the cell. In this study, we investigate the reduction in the capacity of studied LIBs's capacity fade by using a physical model-based simulation for charge-discharge cycles and storage.

The physical-model simulation program provides the charge-discharge voltage profiles by using the experimental potential property of negative and positive electrodes, as well a large number and huge sets of physical and cell design parameters. [3] The electrode potential profiles were obtained by performing a half-cell experiment using with the electrodes taken from the commercial LIB (2.2Ah, composed of  $\text{LiNi}_{0.5}\text{Co}_{0.3}\text{Mn}_{0.2}\text{O}_2$  (NMC) positive and graphite negative electrode). The cell design parameters were measured, and other physical parameters were collected from references and tuned for the discharge voltage profiles of a virgin cell. The charge-discharge test was conducted under the condition of 0.5 C constant current (CC) and 4.2 V constant voltage (CV) mode charge, and a 1.0 C CC mode discharge to 3 V at 45°C. The storage test was carried out at 60°C with a 100% state-of-charge (SOC). The cell capacity was also measured every 100 cycles or 2–4 weeks with a 0.2 C CC-4.2 V CV charge and a 0.2 C CC discharge to 3 V at 25°C. We performed the numerical simulations for these measured discharge voltage profiles was used to determine explore the effect of the cell resistance ( $R_{\text{cell}}$ ) and the usable range of both positive ( $\delta_{p-\text{max}}$ ,  $\delta_{p-\text{min}}$ ) and negative ( $\delta_{n-\text{max}}$ ,  $\delta_{n-\text{min}}$ ) electrodes. The numerical fitting for the cycle test and storage test was successfully realized using the done with those five parameters. The cell resistance  $R_{\text{cell}}$  increased non-linearly with the number of cycles number and storage time. These changes were reproduced by adjusting the cell's positive temperature coefficient (PTC) resistance, (which is a kind-type of safety device possessed by equipped in commercial LIBs having a specific certain resistance). The  $\delta_{n-\text{min}}$  increased with the number of cycles and storage time, while the  $\delta_{p-\text{min}}$  remained stayed almost constant, indicating that the capacity fading in LIBs is due was mainly caused by to the reduction in of the usable range of the negative electrode, as previously studies reported. [4,5] The small change of  $\delta_{p-\text{min}}$  indicated supported that the upper potential point of the positive electrode remained stayed constant in order to sustain the electrochemical stability. The change in the physical properties of LIBs after several cycles and other storage times are being under investigated using physical model simulations.

Rechargeable lithium-ion batteries are among the most promising technologies for various applications such as portable electronics, electric vehicles and power storage system for power grids. The performance of Li-ion batteries is greatly affected by the effectiveness of the solid electrolyte interface (SEI) layer, which is formed on the surface of graphite anode at the first cycle. Use of electrolyte additives is one of the most economic and effective methods for determining, modifying, and improving the formation of an effective SEI layer. Maleimide-based additive is one of the commercial additives that have been shown to improve the capability and cycle-ability due to its high reductive potential compared with carbonates [1-2].

This study evaluates the effects of the fluoro (F-MI) and cyanide (CN-MI) functional groups in maleimide to the SEI formation and the battery performance. Figure 1 shows that 1M LiPF<sub>6</sub> in EC:PC:DEC (3:2:5 in volume) containing 0.1 wt % of CN-MI additives is the most appropriate additives to improvement battery performance. From the charge-discharge curve, it shows that the electrolyte containing O-MI (without functional group), F-MI, and CN-MI additives increase the first discharge capacity by 3%, 3.5%, 4.8% compared with the electrolyte without any additives. Figure 2 shows the discharge capacity is 2.1% (O-MI), 7.1% (F-MI), and 11.7% (CN-MI) greater than the electrolyte without additives after 10 cycles. It indicates that the CN-MI additive is able to form a stable SEI layer and enhances the battery performance.

Figure 1 (a) The first charge discharge curves, (b) Cycle-ability results.

# **The High Performance Silicon Anodes Including New Water Based Binder in Lithium Ion Batteries**

Nam Seon Kim, Soo Jung Kim, Dae Won Park, Gwang Sik Choi  
*Aekyung Chemical Co. R&D Center*  
217-2 Shinseong-dong, Yuseong-Gu, Daejeon 305-805, Republic of Korea

*sunsa@aekyung.kr*

Silicon based negative active material has very high charge capacity and is widely applied to a high capacity battery. However, the silicon based negative active material may expand by about 300% to about 400% during charge and discharge.

Recently much attention has been devoted developing functional binders that can improve adhesion on silicon particle and accommodate substantial volume change during the charge/discharge process to maintain the electrode structure.

The binders for silicon electrodes hold stiff polymeric backbones as like carboxymethyl cellulose (CMC), poly(acrylic acid), and alginate show better electrochemical performance than commercial binders. Despite promising progress, the current research on polymer binders for silicon is still far from the practical application where high mass loading is necessary for the high areal capacity.

Here we report high performance silicon anodes using new water based binder including inorganic binder. This polymer matrix is compatible with lithium ion slurry manufacturing process, and can maintain both electric conductivity and mechanical integrity during the battery operation which results in good stability, rate capability, and cycle-life characteristics at high mass loading ( $>4.5 \text{ mg/cm}^2$ ).

# Development of short-termed and highly effective graphite felt surface treatment process for all-vanadium redox flow battery applications

Donghyun Kil, Hansung Kim\*

\*e-mail: [elchem@yonsei.ac.kr](mailto:elchem@yonsei.ac.kr)

Vanadium redox flow battery (VRFB) is one of the most promising candidates for the large-scale energy storage system [1]. It stores the electrical energy by utilizing different vanadium redox reactions and provides sufficient energy efficiency at lower current density operations. However, at higher current density operations, its energy efficiency drops significantly due to the poor electrochemical activity of pristine graphite felt electrodes. Although several surface modification to enhance electrochemical activity of the graphite felt were proposed [2, 3], many required long treatment time and high energy which is not favorable as it increased overall operating price for VRFBs [4].

In light of this, we devised a novel surface treatment method based on combined use of oxidizing gases and mild heat, which is both fast and low energy consuming [5]. The electrochemical activity of treated graphite felt, and its application as an electrode material for vanadium redox flow battery (VRFB) was investigated. X-ray Photoelectron spectroscopy study revealed that a high concentration of the oxygen functional groups was successfully introduced to the surface of the treated felt which enhanced the wettability and charge transfer property of the electrode. Moreover, the surface roughness of the treated graphite felt increased significantly, which should be advantageous as it can provide abundant surface active site for the vanadium redox reactions to take place. The electrochemical properties of the treated graphite felt were evaluated with cyclic voltammetry and electrochemical impedance spectroscopy, and it was found that the graphite felt treated with just 6 minutes at 180 °C showed best electrochemical activity. When the as-prepared electrode was used as the positive and negative electrode of the VRFB, it was able to retain high energy efficiency even at high current density operation. At 150 mA/cm<sup>2</sup>, VRFB with treated graphite felt maintained energy efficiency of 75.7% which is significantly higher than that of pristine graphite felt (62.0%).

$\text{LiPF}_6$  is widely used lithium salt, which plays a critical role in initiating electrochemical reaction in lithium ion batteries [1]. However,  $\text{LiPF}_6$  suffers from its  $\text{PF}_5$  side reaction, which degrade the solid electrolyte interface (SEI), and lead to formation of  $\text{LiF}$  and  $\text{HF}$  [2]. Due to the Lewis acid basic reaction, benzimidazole-base lithium salt (BZ) which is electrolyte additive can form pentafluorophosphate benzimidazole between the benzimidazole ion and  $\text{PF}_5$ . The pentafluorophosphate benzimidazole anion can inhibit the decomposition of  $\text{LiPF}_6$  by inhibiting  $\text{PF}_5$  side reaction [3].

In order to improve a high ionic conductivity and high voltage application, benzimidazole salt is combined fluoro-functional group. This two kind of new fluorine based benzimidazole salt (1F-BZ & 2F-BZ) are used as electrolyte additives for high voltage lithium-rich ( $\text{Li}_{1.2}\text{Ni}_{0.2}\text{Mn}_{0.6}\text{O}_2$ ) high-capacity cathode [4] of lithium batteries.

In this study, 1M  $\text{LiPF}_6$  in EC/EMC(Blank), 1M  $\text{LiPF}_6$ +0.1 wt% lithium benzimidazole in EC/EMC(BZ), +0.1 wt% lithium fluorobenzimidazole in EC/EMC(1F-BZ) and +0.1 wt% lithium difluorobenzimidazole in EC/EMC(2F-BZ) were used for electrolyte in this research. According to the discharge cyclic performance (Figure 1) of  $\text{Li}_{1.2}\text{Ni}_{0.2}\text{Mn}_{0.6}\text{O}_2$  cathode half cells, which charge/discharge voltage were between 3V and 4.9V, fluorine-benzimidazole salt can improve the cyclic stability of  $\text{Li}_{1.2}\text{Ni}_{0.2}\text{Mn}_{0.6}\text{O}_2$  cathode half cell, and extend the life of battery in operation at high voltage. In addition, Cyclic voltammetry, electrochemical impedance spectroscopy and Scanning electron microscope measurement have been used to characterize the materials in this study.

**Fig. 1.** The discharge cyclic performance of  $\text{Li}_{1.2}\text{Ni}_{0.2}\text{Mn}_{0.6}\text{O}_2$  cathode half cells for Blank, BZ, 1F-BZ and 2F-BZ electrolyte at room temperature. (The 1<sup>st</sup>~7<sup>th</sup> cycle at 0.1C-rate and the 8<sup>th</sup>~22<sup>th</sup> cycle at 0.2C.)

# Polypyrrole as the Coating Agent and Nitrogen Precursor for the Fabrication of Nitrogen-Doped Graphite Felts as Positive Electrode for a Vanadium Redox Flow Battery

Sangki Park, Hansung Kim\*

Dept. of Chemical and Biomolecular Engineering, Yonsei University  
50 Yonsei-ro, Seodaemun-gu, 120-749 Seoul, Korea

\*e-mail: [elchem@yonsei.ac.kr](mailto:elchem@yonsei.ac.kr)

Redox flow batteries operating via the oxidation and reduction of active electrolyte materials have recently received significant attention as electrochemical energy storage systems for renewable energy due to their long life, flexible design, and high energy efficiency [1,2]. Of the various redox flow batteries, vanadium redox flow batteries (VRFBs) are considered to be promising candidates because the same element is used in both half-cells, which avoids crossover contamination of the electrolyte [3,4]. The energy efficiency of VRFB primarily depends on the electrochemical activity of electrode because the redox reaction of vanadium ion occurs on the electrodes surface during charge-discharge process [5,6]. Therefore, it is important to select the suitable electrode materials for VRFB. Carbon-based materials, particularly graphite felt, are widely used as VRFB electrodes because of their high resistance to corrosion in the acidic electrolyte. However, the poor electrochemical activity of graphite felt electrodes remains a technological hurdle for VRFB systems [7]. For this reason, various post treatments of graphite felt including thermal treatment in air, acid treatment, electrochemical oxidation and modification with metal have been applied to enhance the electrocatalytic activity and reversibility of carbon felt electrodes for VRFB. In this study, the graphite felts doped with nitrogen in the presence of transition metal were prepared and studied as positive electrodes in VRFBs. These materials were synthesized by a direct coating of thin layer of polypyrrole (Ppy) on the surface of graphite felt, followed by subsequent carbonization in the presence of transition metal. Impregnation of transition metal to the nitrogen doped graphite felt increased the nitrogen content in the carbon structure during the Ppy pyrolysis, which could improve the catalytic activity towards  $\text{VO}^{2+} / \text{VO}_2^+$  redox reactions. The enhanced performance is attributed to the abundant active nitrogen functional groups created on the graphite felt which are beneficial to the fast electrochemical kinetics of vanadium redox reaction.

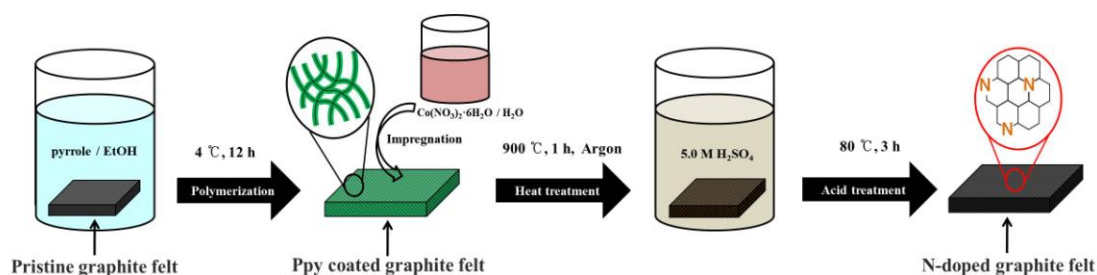

Fig 1. Schematic diagrams of the N-doped graphite felt fabrication process.

# Electrochemical Studies of Tin Film Model Electrode for Magnesium-ion Batteries

Xuan Minh Tran, Dan Thien Nguyen, Seung-Wan Song\*

*Dept. of Fine Chemical Engineering & Applied Chemistry, Chungnam National University  
Daejeon 305-764, Republic of Korea  
swsong@cnu.ac.kr*

Magnesium-ion battery has recently gained a considerable attention as a potential candidate for a next generation beyond-lithium energy storage system, because of its outstanding merit in regard to higher volumetric capacity ( $3833 \text{ mAhcm}^{-3}$ ) than  $2061 \text{ mAhcm}^{-3}$  of lithium [1]), earth abundance, low cost and safety. Nonetheless, due to the formation of magnesium oxide film that blocks the transportation of  $\text{Mg}^{2+}$  ions and restrains a reversible dissolution of  $\text{Mg}^{2+}$  ion and deposition of Mg, the use of Mg metal as an anode has been limited. Extensive research effort has been devoted to find appropriate electrolyte components that permit the reaction reversibility and to improve cycling ability of the anode. The utilization of a new anode material is an alternative choice. Tin had been suggested as one of the alternative anode materials for magnesium-ion batteries [2] but not only a satisfied cycling ability but also a consensus regarding the electrochemical/interfacial reaction behavior have not been achieved. In this presentation, we report the electrochemical studies of tin film model electrode, which is prepared by pulse laser deposition, in magnesium cells.

# Transport properties of $\text{Li}^+$ Mixtures in Two Phosphonium Containing Ionic Liquids

Vitor L. Martins, Nédher Sanchez-Ramirez, Mauro C. C. Ribeiro and Roberto M. Torresi  
*Instituto de Química, Universidade de São Paulo. C.P. 26077, 005513-970 São Paulo (SP), Brazil.*  
*rtorresi@iq.usp.br*

Ionic liquids (ILs) are salt that present melting point below 100 °C and are compound only by ions. This means that they present intrinsic ionic conductivity, which make them interesting alternative to be used as electrolytes. In addition, they present high chemical and thermal stability and extremely low vapour pressure. Among the cations that the IL can be composed, imidazolium is one of the most common and investigated by research groups in different areas, mainly energy storage devices. The anion bis(trifluoromethanesulfonyl) imide ( $\text{Tf}_2\text{N}^-$ ) is also broadly investigated since the ILs composed by this anion present low viscosity and high ionic conductivity, in addition they are hydrophobic. With the aim to apply these ILs as Li-ion battery electrolyte, one must consider the mixture of these liquids with  $\text{Li}^+$  salt, and understand the effect of this addition in the physicochemical properties of the mixture. Many research groups investigated this effect in ILs containing imidazolium and  $\text{Tf}_2\text{N}^-$ . They reported an undesirable effect in the transport properties when the  $\text{Li}^+$  salt is added to the IL. As  $\text{Li}^+$  is added, the viscosity increases resulting in a decrease of the ionic conductivity, comparing to the neat ILs. As the obtained results for imidazolium composed ILs containing the anion  $\text{Tf}_2\text{N}^-$  are not suitable to be used as Li-ion battery electrolyte due to the high viscosity and low ionic conductivity at room temperature, the search for others ILs is still open.

Normally, large phosphonium cations are found in the literature, which have high viscosity, but some small phosphonium were also reported. ILs containing small phosphonium cations present lower viscosity and they are promising for electrolytes application. Phosphonium ILs have lower viscosity and higher ionic conductivity than the ammonium analogues. Also, they have a high electrochemical stability for the neat IL at room temperature and high lithium deposition-dissolution efficiency at 100 °C.

This work presents the physicochemical characterization of two ionic liquids (ILs) with small phosphonium cations, the triethylpentylphosphonium bis(trifluoromethanesulfonyl)imide ( $[\text{P}_{2225}][\text{Tf}_2\text{N}]$ ) and the (2-methoxyethyl)trimethylphosphonium bis(trifluoromethanesulfonyl)imide ( $[\text{P}_{222(201)}][\text{Tf}_2\text{N}]$ ) and their mixtures with  $\text{Li}^+$ . Properties as electrochemical window, density, viscosity and ionic conductivity are presented. The diffusion coefficient was obtained by two different techniques, PGSE-NMR and Li electrodeposition with microelectrodes. In addition, the  $\text{Li}^+$  transport number was also calculated by the PGSE-NMR technique and by an electrochemical approach. The use of these three techniques showed that the PGSE-NMR technique underestimate the diffusion coefficient of charge species. The  $\text{Li}^+$  transport number found is as high as 0.54. Raman spectroscopy and molecular dynamics simulations were used to evaluate the short-range structure of the liquids, they suggested that the interaction between  $\text{Li}^+$  and the  $\text{Tf}_2\text{N}^-$  anion is similar to other ILs containing the same anion. However, the MD simulations also showed that the  $\text{Li}^+$  interact differently with the cation containing an alkyl ether chain.

In summary, the ILs containing phosphonium cations present interesting properties to be considered as electrolytes for Li ion batteries. They present wide electrochemical window, ionic conductivity and even with the  $\text{Li}^+$  addition, the mixtures still present relatively high ionicity compared with ILs containing others cations. The  $\text{Li}^+$  mixture of the IL containing the cation with an alkyl ether chain presents higher ionicity than its analogue with an alkyl chain, as showed by PGSE-NMR,  $\text{Li}^+$  diffusion coefficient and transport number calculation. The Raman spectroscopy suggested that the aggregates formed between  $\text{Li}^+$  and the anion are similar to the aggregates formed in ILs containing others cations. Even the ILs containing an alkyl ether chain and an alkyl chain seems to present similar aggregates. On the other hand, MD simulations showed that despite the number of neighbours of  $\text{Li}^+$  is similar in both ILs, the  $\text{Li}^+$  can be found near the alkyl ether chain with higher probability than near the alkyl chain. The alkyl ether chain presence changes the way that  $\text{Li}^+$  interacts with the IL cation.

# The structural evolution of cathode materials in the current generation of commercial lithium-ion batteries

Neeraj Sharma

*School of Chemistry, UNSW Australia, Sydney NSW 2052 Australia*

[Neeraj.sharma@unsw.edu.au](mailto:Neeraj.sharma@unsw.edu.au)

Li-ion batteries are widely used in portable electronic devices and are considered as promising candidates for higher energy applications. Many challenges, such as energy density and battery lifetimes, need to be overcome before this particular battery technology can be implemented in such applications. To overcome these challenges we need to understand what is happening inside batteries at an atomic level while they function. *In situ* neutron diffraction is performed to probe the crystal-structure of two commercial Li-ion battery cathodes  $\text{Li}(\text{Ni}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3})\text{O}_2$  and  $\text{Li}(\text{Co}_x\text{Ni}_y\text{Al}_z)\text{O}_2$  while they are undergoing electrochemical cycling (charge/discharge) in a battery (see Figure 1). We depict the experimental approach and necessary requirements for the collection of *in situ* neutron diffraction of sufficient standard for thorough and detailed structural analyses of the electrode components of interest within the batteries. *In situ* structural characterisation of the cathode is undertaken under different electrochemical conditions, including varying applied currents and at elevated temperature ( $45^\circ\text{C}$ ). Additionally, the structural consequences for overcharging these cathodes above the limits set by the manufacturer are determined.

Figure 1: Collated *in situ* neutron diffraction data of a commercial lithium ion battery

# **Application of modified rosin-derivatives as promising adhesives for lithium titanium oxide electrodes in lithium ion batteries**

These days, the interest of lithium ion batteries (LIBs) has been gradually shifted to electric vehicles (EV) and energy storage system (ESS) for small mobile devices. It indicates that high-powered LIBs become more and more important as well as high-capacity LIBs. Lithium transition metal oxide is an attractive active material because it is structurally very stable during repeated cycles. Among them, lithium titanium oxide (LTO) has high operating voltage at 1.55 V (vs.  $\text{Li/Li}^+$ ) and no volume expansion, leading to high rate capability and long cycle life.

For this anode active material, we demonstrated the advantages of using rosin, bio-derivative, as a binder additive in our previous study. As a result, when increasing the amount of the rosin additive to the polyvinylidene fluoride (PVdF) binder, the crystallinity of PVdF decreases and ultimately contributes to the increase in the rate capability and capacity of the LTO electrode [1].

In this study, several modified rosin-derivatives are used for the additives of the PVdF binders to improve the cell performance of LTO electrodes. A variety of physical and electrochemical characterization techniques are applied to explain the effect of the rosin-derivative additives.

# Improving the Cycling Performance of the Layered Ni-Rich Oxide Cathode by Introducing the Low-Content $\text{Li}_2\text{MnO}_3$

Jun Yang, Mengyan Hou and Yongyao Xia\*

Department of Chemistry, Shanghai Key Laboratory of Molecular Catalysis and Innovative Materials, Institute of New Energy, Fudan University, Shanghai 200433, People's Republic of China. Fax: +86-21-51630318. E-mail: [yyxia@fudan.edu.cn](mailto:yyxia@fudan.edu.cn)

Recently, Ni-rich layered oxide  $\text{LiNi}_{0.8}\text{Co}_{0.1}\text{Mn}_{0.1}\text{O}_2$  is considered as one of most potential cathode materials for high energy density LIBs due to its larger reversible capacity ( $\sim 200 \text{ mAh g}^{-1}$ ), lower cost and toxicity compared to the commercial  $\text{LiCoO}_2$  cathode<sup>1</sup>. Despite these advantages, Ni-rich layered oxide still presents some intrinsic problems such as the poor cycle property and structure instability upon long-term cycling. So far, numerous efforts have been devoted to further improve electrochemical performance of Ni-based layered oxide cathode material. One strategy is the surface coating of the cathode materials with metal oxides, fluoride, phosphate<sup>2-3</sup>. The coated layer can be served as isolated layer to avoid the side reaction of the cathode surface with electrolyte. In addition, the ion doping and substitution were also considered as an alternative method to improve the electrochemical performance of the cathode materials<sup>5</sup>. Though these modifications have reached a certain effect, one urgent problem still needs to be addressed that the rapid fading of capacity induced by the structure change upon long-term cycling.

**Figure 1.** (a) The first charge-discharge curves and (b) the cycling performance of the as-prepared cathodes between 2~4.5V at a current density of  $20 \text{ mA g}^{-1}$ .

In this paper, introducing the low-content  $\text{Li}_2\text{MnO}_3$  to layered Ni-rich oxide cathode is utilized to improve their cycling performance. The existence of  $\text{Li}_2\text{MnO}_3$  component in the solid solution  $x\text{Li}_2\text{MnO}_3 \cdot (1-x)\text{LiNi}_{0.8}\text{Co}_{0.1}\text{Mn}_{0.1}\text{O}_2$  ( $0 \leq x \leq 0.3$ ) has been testified by XRD, electron diffraction. The  $\text{Li}_2\text{MnO}_3$  component can be served as stabilized species existed in the solid solution when charging to 4.5 V. As a result,  $0.1\text{Li}_2\text{MnO}_3 \cdot 0.9\text{LiNi}_{0.8}\text{Co}_{0.1}\text{Mn}_{0.1}\text{O}_2$  can exhibit more capacity retention of 75% after 100 cycles at  $0.1 \text{ C}$  ( $20 \text{ mA g}^{-1}$ ) between 2~4.5V compared with  $\text{LiNi}_{0.8}\text{Co}_{0.1}\text{Mn}_{0.1}\text{O}_2$  (59 %), which may be ascribed to the stabilized effect of  $\text{Li}_2\text{MnO}_3$  component on the layered structure of Ni-rich oxide cathode.

<sup>b</sup> School of Materials Science and Engineering, Lanzhou University of Technology, Lanzhou 730050, China

Lithium-ion batteries (LIBs) have been commercialized for mobile phones and laptop computers. Recently, LIBs widely expected to drive electric vehicles and hybrid electric vehicles due to their high energy density and power densities, which are in great demand as energy sources and clean energy storage. Transition-metal oxides ( $\text{M}_x\text{O}_y$ , where M is Co, Ni, Fe, Cu, etc.) have emerged as potential anode materials for LIBs because they deliver a theoretical specific capacity far larger than that of commercial graphite material ( $372 \text{ mAh g}^{-1}$ )<sup>[1-2]</sup>. Among these metal oxides,  $\text{Co}_3\text{O}_4$  has attracted great attention due to its high reversible capacities at a relatively low potential, which greatly spurs the rapid development in this field. Unfortunately, the practical application of  $\text{Co}_3\text{O}_4$  in LIBs is still hindered with problems of rapid capacity fading and poor rate capability. In an attempt to overcome these significant drawbacks, it is considered an efficient strategy to design porous/hollow microstructures of  $\text{Co}_3\text{O}_4$  with high surface area and permeability, or coat a thin carbon layer onto the surface of  $\text{Co}_3\text{O}_4$  materials<sup>[3-4]</sup>.

In this work, hierarchical porous  $\text{Co}_3\text{O}_4@\text{C}$  microspheres were successfully synthesized via a template-free method. Firstly,  $\text{Co}_3\text{O}_4$ -based microspheres have been synthesized by a facile ultrasonic spray pyrolysis method. Subsequently, the  $\text{Co}_3\text{O}_4@\text{C}$  composite microspheres have been obtained via a hydrothermal method. As the anodic materials for LIBs, these hierarchical porous  $\text{Co}_3\text{O}_4@\text{C}$  microspheres exhibited enhanced cycling performance ( $986 \text{ mAh g}^{-1}$  at a current density of  $500 \text{ mA g}^{-1}$  after 50 cycles) and high rate capabilities ( $760 \text{ mAh g}^{-1}$  at current densities of  $1000 \text{ mA g}^{-1}$ , respectively) compared with bare  $\text{Co}_3\text{O}_4$  microspheres. This outstanding electrochemical behavior was ascribed to the porosity and carbon coating layers of the  $\text{Co}_3\text{O}_4@\text{C}$  microspheres, which could allow better penetration of electrolyte, achieve a higher reactive area, promote the mobility of ions/electrons and protect the structural integrity of the  $\text{Co}_3\text{O}_4@\text{C}$  microspheres.

Fig. 1 a) SEM image of porous  $\text{Co}_3\text{O}_4$  microspheres. b) SEM image of porous  $\text{Co}_3\text{O}_4@\text{C}$  microspheres (Left) and discharge cycling performance of porous  $\text{Co}_3\text{O}_4$  and  $\text{Co}_3\text{O}_4@\text{C}$  microspheres electrodes at  $500 \text{ mA g}^{-1}$  (Right)

# Self-healing Sn composite lithium-ion battery electrode with high capacity and good cycling stability

Jing Ma, Chaofan Yun, Wang Wang, Xue-Qian Wang, Chun-Ling Liu, Wen-Sheng Dong  
Key Laboratory of Applied Surface and Colloid Chemistry (SNNU), MOE, School of Chemistry and  
Chemical Engineering, Shaanxi Normal University, Xi'an, 710062, China  
ccliutt@snnu.edu.cn

Sn-based materials have been intensively studied as negative electrode candidates for LIB because of their much higher specific capacity (theoretical capacity is  $993 \text{ mAh g}^{-1}$ ). However, these materials suffer from volume expansion/shrinkage during lithium ion alloying/de-alloying. Such morphological changes cause loose contacts between the anode material and the current collector, resulting in poor charge/discharge cycling characteristics.

The biological systems in nature have the ability to self-heal when damaged, we called itself-healing, which is an important survival feature in nature because it increases the life time of living creatures. We can imagine if the volumetric changes of the tin electrode can be cured by itself just like biological systems, the lithium ion batteries will have a high capacity and along cycle life. In order to prepare a self-healing tin electrode, Firstly, we prepared the material that could be self-healing by the interaction of the intermolecular hydrogen bonds. The preparation of repeated destruction and self-healing material included two steps. First, dimer acid reacted with divinyl three amine to obtain the amine oligomer by amidation reaction. Then the product further reacted with urea to form polyamidoamine supramolecular polymer through a series of programmed reaction. Highly branched dendritic structure and a large amount of oriented hydrogen bonds between the molecules made it possible to achieve the self-healing material. Then tin nanoparticles were embedded in this self-healing material, thus successfully preventing the aggregation of tin nanoparticles and buffering the occurring volume strain, which accompanied the reversible (de-)alloying process. Such material presented higher specific capacity and more stable cycling performance, especially when charged at large current density.

**Figure 1.** The cycling performance for SHP/Sn and pure Sn at current density of  $500 \text{ mA g}^{-1}$  (a) and SHP/Sn material at different current densities (b).

The electrochemical characterization of the composites confirmed that SHP/Sn showed excellent electrochemical performance when used as an anode for rechargeable lithium ion batteries. The initial reversible capacity is  $1250 \text{ mAh g}^{-1}$  at a constant current density of  $500 \text{ mA g}^{-1}$ , after 100 cycles it still remained a capacity of  $986 \text{ mAh g}^{-1}$ , which was 78.9% of the first charge capacity.

Daniell cell (i.e. Zn-Cu battery) is widely used in chemistry curricula to illustrate how batteries work, although it has been supplanted in the late 19th century by more modern battery designs because of  $\text{Cu}^{2+}$ -crossover-induced self-discharge and un-rechargeable characteristic. Herein, it is re-built by using a ceramic Li-ion exchange film to separate Cu and Zn electrodes for preventing  $\text{Cu}^{2+}$ -crossover between two electrodes. The re-built Zn-Cu battery can be cycled for 150 times without capacity attenuation and self-discharge, and displays a theoretical energy density of  $68.3 \text{ Wh kg}^{-1}$ . It is more important that both electrodes of the battery are renewable, reusable, low toxicity and environmentally friendly. Owing to these advantages mentioned above, the re-built Daniell cell can be considered as a promising and green stationary power source for large-scale energy storage.

# A high performance lithium-ion sulfur battery based on a $\text{Li}_2\text{S}$ cathode using dual-phase electrolyte

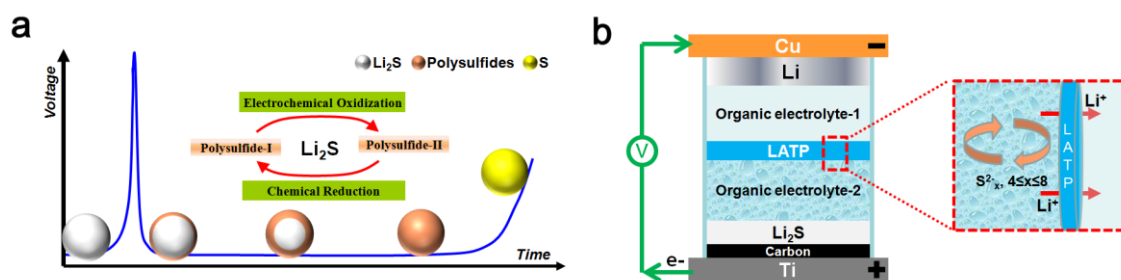

Lina Wang, Yonggang Wang\* and Yongyao Xia\*

Department of Chemistry, Shanghai Key Laboratory of Molecular Catalysis and Innovative Materials, Institute of New Energy, and Collaborative Innovation Center of Chemistry for Energy Materials, Fudan University, Shanghai 200433, China

E-mail: ygwang@fudan.edu.cn; yyxia@fudan.edu.cn.

Fully-lithiated lithium sulfide ( $\text{Li}_2\text{S}$ ) is more desirable than sulfur as a high capacity cathode material because it allows use of a variety of lithium-free anode materials, such as graphite, Si, Al, etc., to form Li-ion sulfur batteries. Unfortunately,  $\text{Li}_2\text{S}$  cathode still suffers from the polysulfides shuttling over discharge-charge cycles. It is worse that  $\text{Li}_2\text{S}$  was considered electrochemically inactive for a long time.<sup>1,2</sup> Lately, Yang et al. demonstrated firstly that  $\text{Li}_2\text{S}$  can be activated after overcoming a huge potential barrier ( $\sim 1$  V) at the beginning of initial charge process.<sup>3</sup> Figure 1a schematically illustrates the activation of  $\text{Li}_2\text{S}$  over initial charge process. The  $\text{Li}_2\text{S}$  cathode must overcome a huge potential barrier at the beginning of delithiation (i.e.  $\text{Li}_2\text{S} \rightarrow \text{Li}_{2-y}\text{S} + y\text{Li}^+ + ye^-$ ). The huge potential barrier then disappears after the outer surface layer of solid  $\text{Li}_2\text{S}$  is electrochemically oxidized into liquid and soluble lithium polysulfides ( $\text{Li}_2\text{S}_x$ ,  $4 \leq x \leq 8$ ). The phenomenon should be attributed to that the lithium bonding environment in  $\text{Li}_2\text{S}$  is more like that in lithium polysulfides than in pure electrolyte, which may facilitate the charge transfer process between  $\text{Li}_2\text{S}$  and the polysulfides.<sup>3</sup> Furthermore, it can be assumed that the further charging after formation of lithium polysulfides includes both electrochemical and chemical reactions. The surface polysulfides ( $\text{Li}_2\text{S}_x$ ,  $4 \leq x < 8$ ) can be further electrochemically oxidized into the longer-chain polysulfides. Simultaneously, the liquid charge product (e.g. longer-chain polysulfides) can also oxidize the solid  $\text{Li}_2\text{S}$  through direct chemical reaction. As mentioned above, the liquid and soluble polysulfides not only improve the charge transfer for solid  $\text{Li}_2\text{S}$ , but also play the role of redox mediators.

Here, we report a new approach to utilize  $\text{Li}_2\text{S}$  efficiently based on a rechargeable Li-S battery with dual-phase-nonaqueous electrolyte, as illustrate in Figure 1b, in which the electrolyte for  $\text{Li}_2\text{S}$  cathode and the electrolyte for anode is separated by a protective lithium super ionic conductor glass film (LISICON) of  $\text{Li}_{1+x+y}\text{Al}_x\text{Ti}_{2-x}\text{Si}_y\text{P}_{3-y}\text{O}_{12}$  (LTAP). The LTAP is permeable to Li-ions while impermeable to polysulfide-anions. As a result, parasitic reactions associated with the polysulfides shuttle effect is totally eliminated in this cell architecture, and the chemistry of the cell can be therefore stabilized. The polysulfides intermediates can be constrained in the cathode apartment to efficiently facilitate oxidation of  $\text{Li}_2\text{S}$ , thus commercially available micro-sized  $\text{Li}_2\text{S}$  without further processing is able to be used as cathode active material directly. The realization of a Li-ion sulfur battery by successfully replacing metallic lithium with aluminum or graphite anode is demonstrated in our initial study.

**Figure 1.** Schematic illustrations. (a) Schematic illustration of activation process of  $\text{Li}_2\text{S}$  cathode over initial charge. (b) Schematic of the architecture for Li-S battery composed of (–) Cu foil/Li metal/organic electrolyte-1/ceramic separator (LTAP)/organic electrolyte-2/ $\text{Li}_2\text{S}$  cathode/Super P carbon/Ti foil (+) from top to bottom.

# Aqueous Lithium-Ion Batteries Using O<sub>2</sub> Self-elimination Polyimides Electrodes

Long Chen, Wangyu Li, Zhaowei Guo, Yonggang Wang, Congxiao Wang and Yongyao Xia\*  
Department of Chemistry, Shanghai Key Laboratory of Molecular Catalysis and Innovative Materials,  
Institute of New Energy, Collaborative Innovation Center of Chemistry for Energy Materials, Fudan  
University

\*e-mail: [yyxia@fudan.edu.cn](mailto:yyxia@fudan.edu.cn)

Lithium-ion (and sodium-ion) battery (LIB and SIB) using aqueous electrolyte may solve the safety problem of LIB using highly toxic and flammable organic solvents. It is also expected to exhibit much longer cycling life than these commercialized aqueous secondary batteries, e.g., lead-acid and nickel-metal hydrogen. Aqueous LIB was first reported by Dahn's group in 1994, the cell could operate at an average voltage near 1.5 V with a specific energy density of 75 Wh/kg based on the total weight of both electrode materials<sup>[1]</sup>. Recently, many efforts have been devoted to develop aqueous lithium-ion batteries, but all have poor cycling stability: the capacity retention is typically less than 50% after 100 cycles. Very recently, we have demonstrated that, the discharged state lithium-ion intercalated compounds (LIC) of any negative electrode candidates for the aqueous lithium-ion batteries would react with water and O<sub>2</sub>, which is the primary cause of the capacity fading upon cycling<sup>[2]</sup>. In principle, the O<sub>2</sub> evolution can be avoided by controlling the cut-off charge voltage and using sealed system. However, it is impossible to absolutely avoid the O<sub>2</sub> evolution using the aqueous electrolyte, especially when the cell was overcharged. On the other hand, taking view of these commercialized aqueous secondary batteries, they could be designed as the sealed system. This is because that the anode electrode material can eliminate O<sub>2</sub> itself if the O<sub>2</sub> evolution occur in the cathode during charge process. Unfortunately, most Li-ion intercalated compounds do not behave the same performance. Very recently, many organic electrode materials have been examined as cathode or anode for non-aqueous LIB or SIB, especially polymers and these multiple carbonyl groups conjugated Quinone and its derivatives with a controlling voltage varying from 1.5 V to 3.0 V vs. Li<sup>+</sup>/Li. In the present work, we interestingly reported that these organic materials, for example polyimide, can not only show excellent Li-ion storage profile in aqueous electrolyte, but also behave the O<sub>2</sub> self-elimination performance (**Fig. 1**): Polyimide electrode can adopt two Li<sup>+</sup> becoming lithiated compound (discharged state). When the cell was overcharged, the O<sub>2</sub> evolution will occur on the cathode, and diffusion into anode, the lithiated polyimide (discharged state) can react with O<sub>2</sub> and be reversibly oxidized into polyimide itself.

**Fig.1** O<sub>2</sub> self-elimination performance and redox mechanism of PNTCDA.

A sealed polyimide-AC/LiNO<sub>3</sub>/LiMn<sub>2</sub>O<sub>4</sub> aqueous LIB exhibited excellent stability with capacity retention over 95% after 1000 cycles at 2C condition, even when the cell was once overcharged.

Recently, TiO<sub>2</sub> nanotubes formed by anodization on Ti foils have attracted great attention as a potential anode material for Li-ion batteries (LIB). This is because the TiO<sub>2</sub> nanotubes provide a high specific surface that benefits the intercalation of Li ions, and Li insertion in TiO<sub>2</sub> occurs at a higher potential (~1.5–1.7 V vs Li/Li<sup>+</sup>) that avoids reduction of Li, thus improving the safety of the LIBs. However, some conducting additive phase have to be mixed into TiO<sub>2</sub> as anode materials for LIBs due to their poor conductive nature. The present study is aimed at fabricating nanoporous TiO<sub>2</sub>-TiN composite films from Ti foils by a tailored anodization in aqueous electrolytes.

Figure 1 shows a representative 3D nanoporous titania film formed by anodizing a Ti foil in a NO<sub>3</sub><sup>-</sup> containing aqueous electrolyte. The anodic titania film composed of multi-tiered nanoporous layers with close-packed cylindrical pores in  $\phi$ 30–60 nm. The tier thickness of porous titania films varied dramatically with the composition of electrolytes, anodizing voltage, and current density. Figure 2 gives the XPS spectra of N1s for the anodized specimen in Fig.1. The spectrum for the film surface showed two peaks corresponding to absorbed ions of NO<sub>3</sub><sup>-</sup> and NH<sup>+</sup>, whereas the spectra after Ar<sup>+</sup> sputtering revealed a new peak close to the binding energy of titanium nitride in TiN, thus confirming the formation of TiN in the anodic titania film. Details on experimental results including FE-SEM, XRD, and electrochemical evaluation as binder-free anode materials for Li rechargeable batteries will be reported on the meeting.

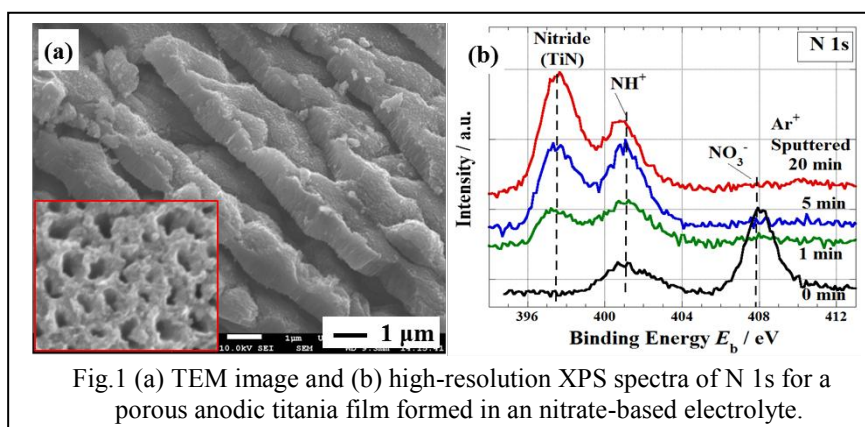

Fig.1 (a) TEM image and (b) high-resolution XPS spectra of N 1s for a porous anodic titania film formed in an nitrate-based electrolyte.

# Electrodeposition of Silicon for the Preparation of Submicrostructured Electrodes

Selina Tillmann, Martin Winter, Isidora Cekic-Laskovic

*MEET Battery Research Center, University of Muenster, Corrensstr. 46, 48149 Muenster, Germany*

*Selina.Tillmann@uni-muenster.de*

In order to advance the replacement of fossil fuel by renewable energy sources, current limitations in energy and power density of lithium-ion batteries need to be overcome. Electrodes offering a large inner surface area combined with good lithium-ion transport properties are promising candidates to improve energy and power density of lithium-ion batteries.[1]

Our approach in this respect is the fabrication of 3-D submicrostructured electrodes based on silicon as active material which is well known for its high theoretical capacity but pronounced volume change during cycling.[2]

In this study we report on the electrodeposition of silicon from an organic solvent suitable for the preparation of nano-/microstructured electrodes and the chemical and electrochemical characteristics of the deposits. Silicon was electrochemically deposited on a nickel current collector by applying a constant potential. Depending on the total current, deposits ranging from several nanometers to a few microns of thickness were obtained. The chemical composition of the obtained silicon films was analysed using X-ray Photoelectron Spectroscopy (XPS), X-ray Diffraction (XRD) and Raman spectroscopy.

To validate the electrochemical performance of the active material, cyclic voltammograms were recorded. Additionally, cycling experiments and the C-rate capability of the electrodes was investigated in half cells using 1M LiPF<sub>6</sub> in EC:DEC 3:7 + 2wt% VC as electrolyte.

Additionally, the effect of the volume expansions during (de)insertion of lithium ions into the deposited silicon was investigated as a function of the thickness of the deposit using Scanning Electron Microscopy (SEM) and XRD.

xiao.huang@kemi.uu.se

Conducting polymers nowadays find widespread use in a range of application areas including organic energy storage, organic light emitting diodes, solar cells, actuators, and bioelectronics.<sup>[1-3]</sup> By introducing functional groups to a conducting polymer backbone, the functionality of conducting polymers can be expanded even further, and the specificity can be increased. In the case of energy storage, the functional groups can *e.g.* yield greatly enhanced specific energies. Herein, we report on the synthesis of a series of building blocks for a new type of low potential conducting redox polymer and their characterization by electrochemical redox property studies including both experimental and computational approaches. These building blocks are composed of thiophene and terephthalate pendant groups connected by various linkers. We observe that the recyclability and reduction potentials are crucially related to the functional linkage between the thiophene and terephthalate subunits. This shows that removing the conjugation between the pendant group and the thiophene backbone could both favor the polymerization and lower the reduction potential of the material. These results constitute the starting point for further studies on a new type of thiophene based low potential redox polymer targeting anode electrode applications.

# Three-Dimensional Activated Porous Carbon /Sulfur Composites as Cathode Materials for Lithium-Sulfur Batteries

Lan Zhou, Tao Huang\*, [Aishui Yu\\*](#)

*Department of Chemistry, Shanghai Key Laboratory of Molecular Catalysis and Innovative Materials,  
Institute of New Energy, Fudan University, Shanghai 200433, China  
[asyu@fudan.edu.cn](mailto:asyu@fudan.edu.cn)*

Lithium sulfur battery, which use sulfur as a cathode and Li as an anode, have taken more and more attention for its high theoretical specific capacity of 1675 mAh g<sup>-1</sup> and high theoretical specific energy of 2600 Wh kg<sup>-1</sup>. Despite these particular advantages, several troublesome issues associated with the sulfur cathode severely limits the practical use of sulfur in an electrode, such as, the highly electrical insulating nature of sulfur, the redox shuttle of dissolved polysulfide ions and the volume expansion of sulfur cathode materials.

In this work, sulfur (S) encapsulated into nitrogen-doped porous carbon nanofiber webs (CNFWs) was obtained by a modified oxidative template route, carbonization-activation and thermal treatment. The sulfur was dispersed and immobilized homogeneously into the micropores of nitrogen-doped porous carbon nanofiber webs (CNFWs) with high electrical conductivity, extremely high surface area and large pore volume, which alleviated the polysulfide shuttle phenomenon and made a contribution to the good electrochemical performance. To further increase the contact area with the electrolyte, three-dimensional flower-shaped activated porous carbon/sulfur composites (FA-PC/S) are also fabricated for the first time via a simple method utilizing flower-shaped ZnO as a template and pitch as the carbon precursor, followed by carbonization-activation and thermal treatment. A typical flower-shaped FA-PC spherical structure is composed of many nanopetals intersecting with one another. Because of the unique three-dimensional flower-shaped porous spherical structure, FA-PC has high reactivity, high electrical conductivity and a short transport length for the Li ion. Furthermore, the rich micropores of the FA-PC offer enough space to accommodate the volume expansion that occurs during the discharge process of the encapsulated sulfur as well as confine the electrochemical reaction products of the sulfur cathode within the micropores. The electrochemical tests show that both three-dimensional activated porous carbon /sulfur composites have a high initial discharge capacity, a good cycling stability and excellent rate capability.

# Carbon-coated $\text{Na}_3\text{V}_2(\text{PO}_4)_3$ Nanocomposite as a Novel High Rate Cathode Material for Aqueous Sodium Ion Batteries

Ludan Zhang, Tao Huang, Aishui Yu\*

*Department of Chemistry, Shanghai Key Laboratory of Molecular Catalysis and Innovative Materials,  
Institute of New Energy, Fudan University, Shanghai 200433, China  
asyu@fudan.edu.cn*

Aqueous rechargeable sodium ion batteries has attracted a lot of interests because of its low cost, huge abundance of sodium resources and promising application for large-scale electric energy storage. Herein, we proposed the carbon-coated  $\text{Na}_3\text{V}_2(\text{PO}_4)_3$  nanocomposite ( $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$ ) as a cathode material, which was prepared using a simple sol-gel method. The structure and morphology analyses showed that the highly crystalline  $\text{Na}_3\text{V}_2(\text{PO}_4)_3$  nanoparticle with an average size of 350 nm is well coated by a carbon layer with a thickness of 3 nm. Electrochemical tests showed that at high current rates, the  $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$  cathode exhibited excellent electrochemical performance. Impressively, it delivered a discharge specific capacity of 94.5 mAh/g at 10C (1176 mA/g), 90.5 mAh/g at 15C (1764 mA/g) and 71.7 mAh/g at 20C (2352 mA/g). To the best of our knowledge, the notable rate capability has never been reported before for aqueous sodium ion batteries. The enhanced electrochemical behavior could be attributed to the combined advantages of  $\text{Na}_3\text{V}_2(\text{PO}_4)_3$  nanoparticles and carbon layer in the unique core-shell structure, which improved the intrinsic poor electronic conductivity of  $\text{Na}_3\text{V}_2(\text{PO}_4)_3$  greatly. Our results confirmed the prepared  $\text{Na}_3\text{V}_2(\text{PO}_4)_3/\text{C}$  nanocomposite should be a promising cathode candidate for aqueous sodium ion batteries.

# Redox Active Polymers: Pursuing a Size-Selective Strategy for High Performance Non-Aqueous Redox Flow Batteries

joaquinr@illinois.edu*

Symposium 3: Batteries for Tomorrow's World

Non-aqueous redox flow batteries (NRFBs) are a potentially viable alternative to their aqueous counterparts as they offer a wider range of redox active species and electrolytes available for their design.[1] However, the low ionic conductivity observed when non-dedicated ion-exchange membranes are used in organic solvents has slowed down their wide-scale implementation. Separating the redox active species in the electrolyte compartments by size-exclusion while allowing free flow of the supporting electrolyte presents a potentially powerful alternative to the use of poorly-performing ion-exchange membranes. In our case, this approach is made possible by the careful design and evaluation of Redox Active Polymers (RAPs), together with porous commercial off-the-shelf separators, as shown in **Figure 1**. RAPs consist of a polymeric unconjugated backbone that is decorated with high energy density and highly stable redox active pendants that display facile electron transfer.

We will present our advances towards implementing such strategy using viologen-, N-oxide-, alkoxybenzene- and nitrobenzene- based redox active polymers (RAPs) with the aim of creating an “ALL RAP” non-aqueous redox flow battery with an open circuit voltage in excess of 2.0 V. Our first studied system, based on viologen RAPs with molecular weight between 21 and 318 kDa exhibited size-dependent transport across the porous separator.[2] This was achieved with RAPs that displayed a high solubility of up to 2.7 M, reversible electron transfer, and 94-99% charge/discharge efficiency. Microelectrode voltammetry allowed to prove facile electron transfer even in highly concentrated solutions (+1.0 M). Preliminary testing using a stirred cell showed the possibility of integrating RAPs and porous separators into a working device that achieved stable charge/discharge and only 2% crossover over several hours. We are working towards the development of guidelines that aid our understanding of RAP electrochemistry. The application of new electrochemical and ionic imaging methods based on scanning electrochemical microscopy using micro- and nano- electrodes developed in our group [3] has allowed us to better understand the careful balance between RAP size and ion and electron mobility. We will discuss how these guidelines have significantly aided our molecular design and how they impact the performance of this new type of flow batteries.

# Search for Perfect Carbonaceous Sulphur Hosts for Li–S Batteries

Sigita Urbonaite, Petr Novák

*Electrochemical Energy Storage Section, Electrochemistry Laboratory, Paul Scherrer Institute,  
5232 Villigen PSI, Switzerland  
sigita.urbonaite@psi.ch*

Lithium–sulphur batteries have been studied for several decades, motivated by predictions of a high specific charge of 1672 mAh/g and a high specific energy of 2,500 Wh/kg [1]. They are among the most promising systems for the next generation of rechargeable lithium batteries. However, the development of Li–S batteries faces a number of challenging problems on the way to reaching maximum performance and commercialization. One of them is the insulating nature of sulphur, necessitating the addition of conductive additives to the electrode material. Whereas a wide range of factors contribute to the overall performance of the Li–S system [2], reported optimization procedures typically focus on the development of novel structured cathodes, in which the conductive environment of sulphur is optimized. The most widely used conductive additive for electrodes is carbon, many different forms of which are being employed for positive electrodes in Li–S batteries [3–6]. The perfect carbon host for accommodating sulphur would, of course, have to provide electronic conductivity, but it should also help in maintaining a high specific charge and high coulombic efficiency by containing polysulfides, as to suppress the polysulfide shuttle and loss of active material.

Here we present a systematic study of various commercially available carbons used as hosts for S in positive Li–S battery electrodes. The influence of pore volume, pore-size distribution and surface area on the performance of Li–S cells was investigated in combination with several S impregnation/infiltration methods (morphologies of C–S composites and sulphur distribution after its impregnation/infiltration using the different methods are shown in the figure below). Correlations between cycling performance of Li–S cells and properties of carbons on the one hand and impregnation methods on the other hand are shown. It was found that predominantly mesoporous materials with their open structure lead to the best specific charge and capacity retention during cycling. In contrast, highly microporous carbons displayed poor specific-charge values and fast specific-charge fading over the cycling duration.

sebastien.sallard@psi.ch

The research on positive electrode materials for Li-ion batteries has generally been focused on inorganic compounds such as transition metal oxides, phosphates or silicates. The variety of different purely inorganic compounds is however limited. Introducing an organic component into the inorganic framework would give rise to various new synthetic possibilities and might therefore in the future allow adjustments of the electrochemical properties of the metal ions by the influence of neighboring organic groups. Only few examples of such organic-inorganic hybrid materials are known in the literature. The most promising already reported example of a positive electrode material for Li-ion batteries where a rigid organic group was implemented to define the structure is  $[\text{Fe(III)(OH)}_{0.8}\text{F}_{0.2}(\text{bdc})]\cdot\text{H}_2\text{O}$  developed by G. Férey et al.<sup>1</sup>

To introduce a new class of organic-inorganic hybrid materials for Li-ion batteries with versatile organic parts, we chose to investigate transition metal diphosphonates. The material lithium iron methylene diphosphonate was selected as reference material as proof of concept for hybrid materials for positive electrode in Li-ion batteries.

Lithium iron methylene diphosphonate was synthesized by a simple hydrothermal route, yielding a material with a new crystalline phase. In a half-cell configuration, it exhibits a specific charge of 90 mAh/g upon lithiation (reduction), which remains stable for more than 100 cycles (Figure 1). The specific charge even continuously increases after 60 cycles to reach a value of 118 mAh/g after 160 cycles. The large irreversibility of the first and the second cycle with a different potential profile is assumed to originate from the removal of residual  $\text{H}^+$  in the structure upon delithiation, leading to enhanced electrolyte decomposition. The consecutive delithiation steps do not any longer show this feature, thereby increasing the coulombic efficiency drastically from very low in the first cycle ( $\sim 40\%$ ) to a more reasonable value ( $> 90\%$ ) after 10 cycles, reaching a stable value of 97% after 50 cycles. *Operando* XANES confirmed the oxidation and reduction of iron during the cycling.

The results obtained provide a basis for investigations on the influence of different heteroatoms or organic entities substituted to the diphosphonate on the electrochemistry of the hybrid material, which is the focus of our future research.

**Figure 1 left:** Galvanostatic profile of lithium iron methylene diphosphonate cycled in a half-cell configuration. After each half-cycle, a 1 h potentiostatic step was implemented. **Right:** The corresponding evolution of the specific charge during cycling of lithium iron methylene diphosphonate.

# Polymer Binders Evaluation for Improved Lithium-ion Batteries Positive Electrodes via Water-based Processing Route

A. Robba, D. Sotta, S. Chazelle, M. Chami, S. Jouanneau Si Larbi  
CEA, Department for Electrical and Hydrogen Transportation (LITEN/DEHT/SRGE),  
17 rue des Martyrs, F-38054 Grenoble Cedex 9, France  
e-mail address: [dane.sotta@cea.fr](mailto:dane.sotta@cea.fr)  
*Symposium 3: Batteries for Tomorrow's World*

Lithium-ion batteries have now spread as the leading energy storage technology for a wide variety of applications such as portable electronics, electrified transportation and stationary systems. Research efforts attempt to decrease their overall cost and environmental impact by considering eco-friendly design and process from material synthesis to batteries recycling [1,2]. Water-based process for electrode manufacturing is now used at industrial scale for anodes but it is far less developed for cathodes due to several issues such as material sensitivity towards water and aluminum current collector corrosion during coating process [3,4].

Here we report electrode formulations evaluations using lithium nickel-manganese-cobalt lamellar oxide ( $\text{LiNi}_{1/3}\text{Mn}_{1/3}\text{Co}_{1/3}\text{O}_2$ , NMC) as active material and several polymer binders for water-based suspensions. Slurry manufacturing was improved by adding acidification step aimed at decreasing suspension pH and thus avoiding aluminum pitting when coating. NMC analysis with XRD and ICP-MS didn't show any impact of slurry acidification on material structure. The addition of latex binder at the end of slurry manufacturing was privileged as a well-established means to improve electrode mechanical properties (adhesion on current collector, flexibility). Styrene-butadiene rubber emulsion (SBR) was tested as the reference latex for water-based formulations, but it exhibited poor electrochemical stability at cathode high voltages. This degradation due to polymer oxidation led to poor cycling performances in coin cells. On the contrary a non-SBR latex such as "latex 2" exhibited satisfying performances when compared to reference electrodes using PVdF as a binder (Figure 1). The combination of slurry acidification and proper latex selection is thus thought as an effective way to improve aqueous formulations for cathodes.

Figure 1 : C/2 discharge capacity upon cycling in half coin-cells NMC/Li (1.3 mAh/cm<sup>2</sup> NMC loading, [3-4.35 V vs.  $\text{Li}^+/\text{Li}$ ] voltage range, room temperature)

# **BaZr<sub>x</sub>Ce<sub>0.8-x</sub>Y<sub>0.2</sub>O<sub>3-δ</sub> (x = 0.5, 0.6, 0.7) Proton Conductors Prepared by Spark Plasma Sintering**

Junfu Bu, Pär Göran Jönsson, Zhe Zhao

*Department of Materials Science and Engineering, KTH Royal Institute of Technology, SE-100 44*

*Stockholm, Sweden*

[junfu@kth.se](mailto:junfu@kth.se)

Dense BaZr<sub>x</sub>Ce<sub>0.8-x</sub>Y<sub>0.2</sub>O<sub>3-δ</sub> (x = 0.5, 0.6, 0.7) proton conductors, which can be used for intermediate temperature solid oxide fuel cells (ITSOFCs), were successfully prepared by Spark Plasma Sintering (SPS) at 1350 °C without sintering aids addition. Though SPS had been used for various ceramic preparation, there is no success case for preparation of dense Ce-containing BaZr<sub>0.8-x</sub>Ce<sub>x</sub>Y<sub>0.2</sub>O<sub>3</sub> (0 < x ≤ 0.8) or BaZr<sub>0.9-x</sub>Ce<sub>x</sub>Y<sub>0.1</sub>O<sub>3</sub> (0 < x ≤ 0.9) based proton conductors as far as we know. This is due to the Ce<sup>4+</sup> reduction in a reducing atmosphere. Therefore, it is really a meaningful and tough work to realize a preparation of high-quality Ce-containing BaZrO<sub>3</sub>-BaCeO<sub>3</sub> based proton conductors by using the SPS technique.

In this work, the prepared dense BaZr<sub>x</sub>Ce<sub>0.8-x</sub>Y<sub>0.2</sub>O<sub>3-δ</sub> (x = 0.5, 0.6, 0.7) proton conductors were characterized by XRD, SEM and EDS, in order to determine phase purity, morphology and element composition of prepared pellets, respectively. In addition, the conductivities of these samples were determined at different atmospheres: dry air, wet N<sub>2</sub> and wet H<sub>2</sub>. Moreover, the potential electronic conduction contribution to the total conductivity was also identified by using different oxygen partial pressures (1 - 10<sup>-24</sup> atm) in combination with an XPS analysis. Several important achievements were obtained in this work and these achievements should have positive promotion for present ITSOFCs, such as:

- (1) The sintering temperature was lowered by 300 °C without sintering aids addition compared to conventional sintering.
- (2) This lowered sintering temperature can significantly improve the electrode and electrolyte co-fired preparation, and this will maintain the porous properties of electrode as well as the dense properties of electrolyte.
- (3) The obtained conductivity data shows that the materials can be used as proton conductors for ITSOFC applications. Moreover, it was found that the electronic contribution to the total conductivity can be neglected after the analysis of the total conductivities at different oxygen partial pressures combined with an XPS analysis.
- (4) Furthermore, the relative density of the prepared BZCY532 pellet is 0.995 and the grain size has a narrow distribution (400 - 500 nm). The pore-free microstructure promised a serious study on the proton conductivity without the potential influence of pores. And the fine grain size of 400 - 500 nm promised the better mechanical strength for thin electrolyte SOFC cell structure. In our opinion, this work should be an important improvement in preparation of BaZrO<sub>3</sub>-BaCeO<sub>3</sub> based proton conductors.

# Towards Control of Major Degradation Processes in Solid Oxide Electrolysis Cells

Sergey N. Rashkeev,<sup>1,\*</sup> Michael V. Glazoff,<sup>2</sup> Stephen J. Herring<sup>2</sup>

<sup>1</sup>*Qatar Environment & Energy Research Institute, P.O. 5825 Doha, Qatar*

<sup>2</sup>*Idaho National Laboratory, Idaho Falls, ID 83415, USA*

\*e-mail: [srashkeev@qf.org.qa](mailto:srashkeev@qf.org.qa)

Materials used for different components (electrodes, electrolyte, steel interconnects, etc.) of solid oxide electrolyzer cell (SOEC) devices for hydrogen production have to function in aggressive, corrosive environments and in the presence of electric fields. This results in a number of degradation processes at interfaces between components. In this study, we used a combination of first-principles, density-functional-theory (DFT) calculations, and thermodynamic modeling to elucidate the main processes that contribute into the two major degradation mechanisms in SOECs: (i) delamination of oxygen electrode in typical SOEC device consisting of yttria-stabilized zirconia (YSZ) electrolyte and Sr-doped LaMnO<sub>3</sub> (LSM) oxygen electrode, and; (ii) vaporization of Cr-rich volatile species from interconnect materials.

We found that high temperature inter-diffusion of different atomic species across the LSM/YSZ interface significantly affects structural stability of the materials and their interface. In particular, we found that La and Sr substitutional defects positioned in ZrO<sub>2</sub> oxide and near LSM/YSZ interface significantly change oxygen transport which may develop pressure buildup in the interfacial region and eventually develop delamination process. Simple models for estimating these effects are proposed, and different possibilities for inhibiting and/or mitigating undesirable delamination processes are discussed. In particular, we discuss possible modifications of operational regimes for SOEC devices. It is shown that applying alternating current (AC) voltage pulses with specific shapes and at a certain frequency range to SOECs could significantly reduce oxygen delamination in these devices and increase their lifetime. This operational scheme provides wide possibilities to increase longevity of SOEC devices required for their use in commercial hydrogen production processes, without any significant modification of used materials and/or cell design. Developed simulation method possesses a broad generality and be employed in a number of other industrial processes.

Vaporization of Cr-rich volatile species from interconnect materials is another major source of degradation that limits the lifetime of planar solid oxide devices systems with metallic interconnects such as Solid Oxide Fuel Cells (SOFC) and Solid Oxide Electrolysis Cells (SOEC). Some metallic coatings (Ni, Co, and Cu) may significantly reduce the Cr release from interconnects and slow down the oxide scale growth on the steel substrate. To shed additional light upon the mechanisms of such protection and find a suitable coating material for ferritic stainless steel materials widely used for interconnects, we used a combination of first-principles calculations, thermodynamics, and diffusion modeling to investigate which factors determine the quality of the Ni metallic coatings. We found that Cr migration in Ni coatings is determined by a delicate combination of the nickel oxidation, Cr diffusion, and phase transformation processes. Although the formation of Cr<sub>2</sub>O<sub>3</sub> oxide is more exothermic than that of NiO, the kinetic rate of the chromia formation in the coating layer and its surface is significantly reduced by the low mobility of Cr in nickel oxide and in NiCr<sub>2</sub>O<sub>4</sub> spinel. These results are in a good agreement with diffusion modeling for Cr diffusion through the Ni coating layer on the ferritic 441 steel substrate.

As increasing power density and performance of polymer electrolyte membrane fuel cell (PEMFC), this system has been applied to the Unmanned Aerial Vehicle (UAV) as a power source. Especially, HALE (high altitude and long endurance) UAVs have various applications which are not only military missions like surveillance but also commercial needs such as meteorological observation, aerial photograph, and internet network build. To realize these great potentials of HALE UAV, high energy density and specific energy power generator should be needed. The fuel cell power module has gained recognition as one of the most possible candidate. However, many technological huddles lie ahead, for example, thermal and water management in the extreme atmospheric environment of stratosphere, ultra-light manufacturing technology for fuel cell stack and BOPs, and high energy density fuel containing method. In this work, the fuel cell system design for the UAV was discussed in terms of operating conditions under conditions of extreme low temperature and pressure, lightening method of stack, and enhancing performance of membrane and electrode assembly and stack.

# Modeling of Structure Formation and Fracturing in Polymer Electrolyte Membranes

Polymer electrolyte membranes (PEMs) play a key role as separator and proton transport media in electrochemical energy technologies, most prominently in polymer electrolyte fuel cells (PEFCs). Current membranes require sufficient hydration for efficient proton conduction. The self-organized structure of the membrane, formed from comb-shaped ionomers with acid-terminated sidechains, dictates its water sorption behavior, transport properties, durability and lifetime. In spite of decades of research, this structure has remained controversial. The first part of this contribution focuses on ionomer bundle formation in water. We will present results of a recently developed theory [1] and of molecular dynamics simulations. The strengths of hydrophobic and electrostatic interactions are varied to explore their effect on the aggregation process, as illustrated in Figure 1. The bundle network morphology is the basis for a model of fracture formation in PEMs, discussed in the second part. The fracturing process is mapped onto a lattice percolation problem. Bundle breaking in the lattice is the elementary breaking step. At the lattice level, various regimes fracture formation exist, depending on the strength of correlations between elementary breaking events. The limit with weak correlations is the random percolation regime. Strong correlations lead to a nucleation regime, with a clear-cut fracture line, through an avalanche regime, characterized by sudden bursts of elementary breakages. An important aspect of this modeling work is to relate these regimes to physical parameters describing the material. In the random percolation regime, the time to formation of a sample-spanning fracture is analytically derived as a function of bundle properties and the local stress distribution.

**Figure 1.** Changes of the average aggregate size,  $\langle k \rangle$ , as a function of variation in strengths of hydrophobic interactions (a) and electrostatic interactions (b).

# Shorting in Proton Exchange Membrane Fuel Cells

Yeh-Hung Lai\* and Corey Schaffer

*General Motors Company*

*895 Joslyn Ave*

*Pontiac, MI 48340*

*U.S.A.*

*\*yeh-hung.lai@gm.com*

Ohmic shorting through the membrane has been identified as one of the major failure modes in Proton-Exchange-Membrane fuel cells (PEMFC) [1]. Shorting occurs when electrons flow directly from the anode to the cathode instead of through the device being powered. Ohmic shorting not only can reduce the PEMFC performance, but also can lead to local heat generation in the vicinity of the short, causing membrane damage that can ultimately result in gas crossover failure. Two types of membrane shorts have been observed during the fuel cell testing: soft shorts and hard shorts. A soft short is a sub-critical short that results from the conductive carbon fibers or debris penetrating through the membrane. The soft shorts do not immediately lead to fuel cell failure; however, significant accumulation of soft shorts can reduce the overall cell resistance and compromise fuel cell durability through cell voltage degradation. A hard short is a critical short that is the result of significant heat release from an existing soft short. A hard short can directly lead to membrane crossover and cell failure. Hard shorts occur suddenly in an operating fuel cell stack where one cell develops a cell voltage reversal well below -1 V [2].

The present study is composed of two major parts. The first is to investigate the fuel cell operating conditions that lead to cell reversal and hard shorts. The second is on the development of a test method to determine the number and severity of soft shorts that may result in hard shorts when these adverse fuel cell conditions are met. The ultimate objective of the study is to prevent the PEM fuel cell shorting failure through better material designs and fuel cell operation controls.

In the first part of the study, we stepwise dried out a single large-active-area fuel cell by decreasing the inlet gas dew points while under galvanostatic control. At a critical dew point, the cell potential dropped rapidly to reach a negative voltage that we limited to -1 V. No electronic short or any observable damage to the cell was detected in this experiment. Tests were conducted at various cell current densities and inlet temperatures, which showed that the corresponding cell resistance at the onset of rapid cell voltage drop decreases as the current density increases or as the temperature decreases. Good correlation is found between the cell resistance and the onset of cell reversal at various current densities. When the cell reversal limit of -1V was removed, we found that hard shorts can develop at a cell voltage around -3V, confirming the importance of operating the fuel cell within the operating window developed in this study.

In the second part of this study, we have proposed the use of a current distribution circuit board [3] in a fixture that induces uniform compression over a 32 cm<sup>2</sup> area of a sample that consists of a piece of proton exchange membrane or a membrane electrode assembly sandwiched between two layers of gas diffusion layers. By incrementally increasing the compressive pressure and subjecting the sample to a voltage of 0.6 V, we can measure increasing shorting currents in some of the 0.5 cm<sup>2</sup> current distribution segments. By de-convoluting the current density distribution measured in this experiment, the number and severity of each short can be identified and the robustness of various material sets against soft shorts can be compared.

The operation of proton exchange membrane fuel cell (PEMFC) is limited by the slow reaction of oxygen reduction reaction (ORR) at cathode side,<sup>[1]</sup> which is traditionally solved by using platinum catalysts. However, platinum utilization is limited by its natural abundance and high cost. Therefore, the replacement of platinum with an efficient, durable, and inexpensive material is currently one of major research efforts in fuel cell development.

Non-precious metal catalyst is one of potential materials for cathode applications. Transition metal macrocyclic compounds, such as porphyrin, phthalocyanine, tetraazannulene and polypyrrole have been reported to be good cathode materials.<sup>[2-4]</sup> Among these compounds, Fe- and Co-based macrocyclic compounds have been reported to have the high catalytic activity for ORR.<sup>[5, 6]</sup> This work demonstrates the non-precious metal catalyst by using folic acid as a new nitrogen precursor mixed with iron and carbon black for fuel cell application. The ORR measurements reveal that the optimized condition of catalyst shows an excellent ORR activity, and the electron transfer number and %H<sub>2</sub>O<sub>2</sub> is 3.99 and 0.5%, respectively. The ORR mechanisms have to be investigated furthermore.

One of the promising approaches to reduce the content of platinum in the Pt/C catalysts for the oxygen electroreduction reaction (ORR) in polymer electrolyte fuel cells (PEMFC) is to increase the activity and Pt utilization by optimizing the morphological properties and the structure of the porous carbon supports. In recent decades, nanostructured carbon supports - carbon nanotubes and nanofibers received much attention because of the higher electrical conductivity and the effective mass transport properties.

In this work we synthesized a series of 20 and 40 mass % Pt/C electrocatalysts based on commercial carbon blacks and nanostructured carbon supports: the original and the modified multiwall carbon nanotubes (CNTs), catalytic filamentous carbon (CFC) and commercial carbon blacks. The Pt particle sizes were found in the 2.8 – 12 nm range, as obtained from the TEM studies and gas-phase CO chemisorption measurements. The electrochemically active surface of Pt in the Pt/C catalysts was calculated using the electrooxidation of chemisorbed CO. The mass and surface activities as well as the activation energies in the ORR were obtained by rotating disc electrode in the 10-35 °C temperature range in 0.1 M HClO<sub>4</sub> solution.

It was found that the mass and surface activities depend strongly on the porous and morphological carbon properties. The ORR activity of 40 mass. % Pt/CNT was greatly improved as compared to the commercial sample (20 mass. % Pt/Vulcan XC-72).

CNT support was modifying by carbon deposition in order to increase Pt dispersion. 20 mass. % Pt/C catalysts prepared on modified carbon support showed the higher ORR activity as compared to the unmodified carbon.

The effect of the Pt particle size and morphology and texture of carbon supports on the ORR activities of Pt/C catalysts is discussed in the paper.

Authors thank Dr. Kazakova M. and Dr. Voropaev I. for the provided carbon materials. This work was supported by the RFBR grant № 13-03-01023. The work is also supported by the Ministry of Education and Science of the Russian Federation”.

# Novel Pd-Fe-Co Core-Core-Shell Anode Nanocatalyst in Alkaline Anion-Exchange Membrane Alcohol Fuel Cells

**Kenneth I. Ozoemena**<sup>\*,1,2</sup>

Nanostructured electrocatalysts are extremely important for the development of high-performance alcohol direct alkaline fuel cells (ADAFCs). The use of microwave irradiation to tune the physico-chemical properties of inorganic materials has been known for some decades. However, there is a limited literature on the use of microwave irradiation to control the structure, size and electrochemistry of nanocatalysts for fuel cells. To close this knowledge gap, we have been investigating novel synthetic technique involving microwave irradiation which we termed “microwave-induced top-down nanostructuring and decoration” (MITNAD) for making Pd-based ternary core-shell nanoparticles (FeCo@Fe@Pd/C) with sub-10 nm diameter size for the development of ADAFCs [1-3].

In our most recent study [3], we investigated the performance of FeCo@Fe@Pd core-core-shell nanocatalyst, supported on carboxylate-functionalized multi-walled carbon nanotubes (MWCNT-COOH), as anode catalyst for passive and active anion-exchange membrane direct polyhydric alcohol fuel cell (AEM-DPhAFC). The two polyhydric alcohols investigated were glycerol (Gly) and ethylene glycol (EG). Using nuclear magnetic resonance (NMR), we analyzed the exhaust products of the AEM-DGFC operated at low temperatures and proved that the FeCo@Fe@Pd/MWCNT as anode exhibits high selectivity towards the complete and exhaustive oxidation of polyhydric alcohols. This presentation will discuss all our recent findings on the electrocatalytic properties of FeCo@Fe@Pd/MWCNT for application in AEM-DPhAFC.

# Is the Tafel approximation sufficient to predict electrocatalyst performance in polymer electrolyte fuel cells?

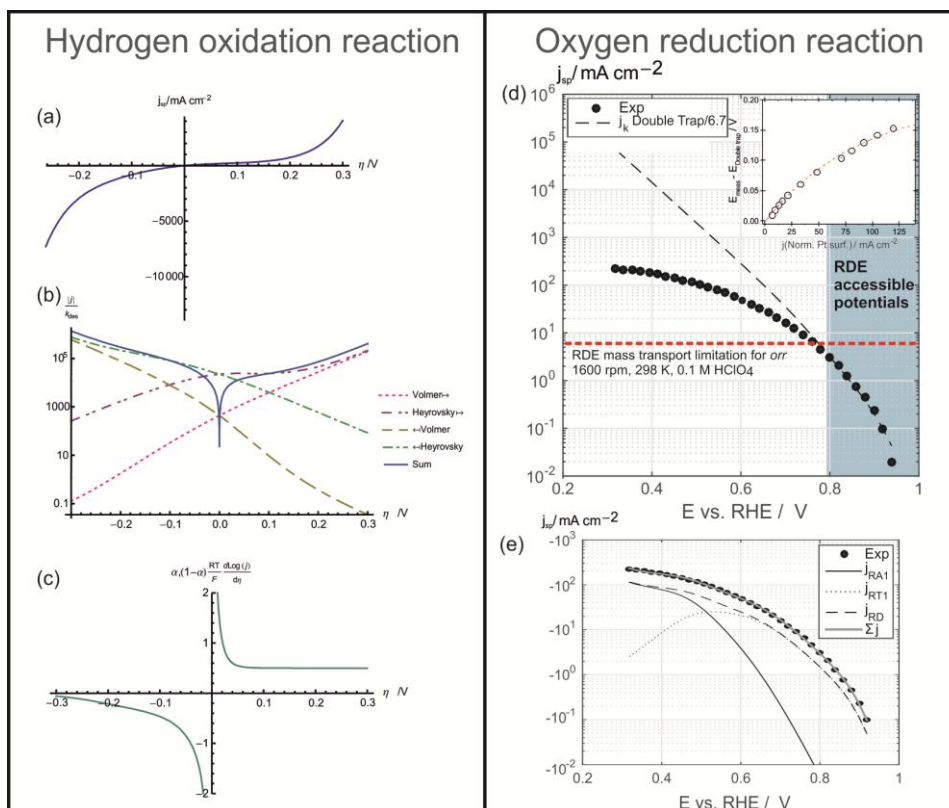

Anthony Kucernak, Matthew Markiewicz, Christopher Zalitis

Imperial College London

Imperial College Rd, London, SW7 2AZ, United Kingdom

a.kucernak@imperial.ac.uk

Description of fuel cell electrocatalysis typically involves approximations to the underlying governing formulae. For instance, it is often assumed that at large overpotentials we may use the Tafel approximation – that is that the reaction under study is controlled by one electron transfer step across a relatively large range of potentials, and that the surface remains relatively invariant across that potential regime. Such an approach is typically used to describe oxygen reduction reaction (*orr*). Alternatively, a Butler-Volmer type dependence close to the reversible potential is often assumed e.g. for the hydrogen oxidation reaction (*hor*). Parameters for these models are often obtained by extrapolating the performance achievable at a rotating disk electrode (RDE) under severe mass transport limitation. However, mathematical tools have moved on considerably since the advent of electrochemical kinetics, and it is now possible to analytically solve many important surface limited reactions. Recently we have developed a new method of measuring electrocatalyst performance under conditions of high mass transport [1, 2]. We have used this approach and electrochemical modelling to understand important aspects of the *hor* and *orr* [3, 4]. Examples are given in Figure 1 (a)-(c) in which analytical solutions for the *hor* may be used to follow the different components of the reaction at different overpotentials and understand the regions in which limiting Tafel slopes may occur. Similarly for the oxygen reduction reaction modelling of the electrochemical reaction is possible only when a blocking species is present on the electrode at high overpotentials Figure 1 (d)-(e). This paper will discuss the relevance of these results to modelling of the *hor* and *her* in fuel cells.

*alexandra.patru@psi.ch*

Up to date, the literature reports stability studies for new oxide catalyst supports for Polymer Electrolyte Fuel Cell (PEFC) cathodes where the degradation protocols are generally realised at the laboratory, liquid electrolyte cell level (room temperature, non-optimised catalytic layer) [1]. Only few data are available regarding the processing of this new alternative supports for Pt in a PEFC and the stability under real operating conditions of the derived Membrane Electrode Assemblies (MEAs).

In this context, this work addresses the long-term stability issues of PEFCs based on a new cathode catalyst generation. Commercial Pt/IrTiO<sub>2</sub> (Umicore®) and home-made Pt/Sb-doped SnO<sub>2</sub> (SbSnO<sub>2</sub>) were used as new cathode catalysts and referenced to the properties of standard Pt/C (TKK) on the single cell MEA level.

The fuel cell performances and stabilities of the various MEAs are examined in differential cells (small-size single cells operated at high stoichiometry) [2]. Accelerated stress test protocols, e.g., potential or start-stop cycling were applied to the different home-made MEAs. The different contributions to the overall cathode overpotentials i.e., kinetic and mass transport losses inside the catalyst and the gas diffusion layers, respectively, are separated with the help of pulsed oxygen and helox operation, a method recently developed in our group [3], throughout the accelerated stress tests. Structural changes of the electrodes are furthermore monitored by electron microscopy. Thus study demonstrates the benefits and drawbacks of oxide support materials for PEFC cathodes.

Email: lgan@sz.tsinghua.edu.cn

Shaped platinum (Pt) alloy nanoparticles (e.g. Pt alloy nanooctahedra) represent a class of highly active oxygen reduction electrocatalysts for fuel cells.<sup>1,2</sup> While different methods have been developed for preparing Pt alloy nanooctahedra, they showed vastly different electrocatalytic properties.<sup>3,4</sup> Understanding the nanoparticle growth mechanism is essential for rational syntheses of shaped Pt bimetallic nanoparticles with desired electrocatalytic properties.

In this talk, we present some of our recent works on understanding and possible controlling ways of the anisotropic growth mechanism and the associated electrocatalytic properties of Pt-Ni octahedral electrocatalysts by using state-of-the-art aberration-corrected scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS). Our results reveal a novel element-specific anisotropic growth mechanism of Pt bimetallic nano-octahedra where compositional anisotropy couples to geometric anisotropy.<sup>5</sup> A Pt-rich phase evolves into precursor nano-hexapods followed by a slower step-induced deposition of a M-rich (M=Ni, Co, etc.) phase at the concave hexapod surface forming the octahedral facets. The element-specific anisotropic growth provides the origin of previously reported compositional segregation (Ni-rich facets and Pt-rich corners/edges) and chemical degradation pathway of the Pt-Ni octahedra, which underwent a selective etching of the Ni-rich {111} facets and thus activity instability during the ORR electrocatalysis in acidic electrolyte. Furthermore, we explored possible ways for tailoring the element-specific anisotropic growth trajectories to improve the electrocatalytic activities and stabilities of the Pt alloy nanooctahedra. Our results provide a comprehensive understanding on the atomic-scale “life-cycle” model of the Pt bimetallic nanooctahedra electrocatalysts and provide useful insight into rational catalyst designs with desired phase segregations and electrocatalytic properties.

Anode compositions made of  $(\text{La}_{0.75}\text{Sr}_{0.25})_{0.97}\text{Cr}_{0.5}\text{Mn}_{0.5}\text{O}_3$  (LSCM) and gadolinia doped ceria (CGO) with and without additional submicron Ni, or exsolved Ni nanoparticles were characterized by electrochemical impedance spectroscopy. Thus, increasing the content of the ionic conductor results in a decrease of the impedance in the frequency range [100 Hz - 10 Hz]. The effect of the catalyst component was studied while maintaining the same electronic conductivity in the tested materials. Enhanced catalytic activity was shown to greatly decrease the impedance, especially in the frequency range [100 Hz - 1 Hz]. Moreover, the effects of the working temperature and the anode gas flow rate were studied. It appears that increasing the gas flow rate results mainly in an important decrease of the impedance from 1 Hz to 0.01 Hz. Besides, increasing the temperature leads to a very important decrease of the whole impedance, meaning that all the main electrochemical mechanisms related to the cell functioning are thermally activated.

Solid electrolytes exhibit electrical conductivity due to the presence of mobile ions which act as charge carriers through the crystalline structure. For their use in solid oxide fuel cells (SOFCs), a sufficient electrical conductivity is achieved by operating at high temperatures. To reduce the application temperature, research is dedicated to increase the electrical conductivity of the ceramic material otherwise. One way is reducing the grain size. At present it is not clear how the microstructure of solid state electrolytes affects the electrical conduction. In literature, the experiments on nanocrystalline solid oxides yield contradictory observations. A good understanding of the relationship between microstructure and ion conductivity would open the possibility to engineer advanced thin materials for SOFCs.

We propose an experimental and modeling approach that aims at unraveling the electrical behavior of thin film electrolytes, by considering the crystalline nature of the material. Through careful comparison of simulations and measurements we want to explain the observed electrical properties of these materials to predict how their conductivity can be enhanced.

The complex electrical properties at different temperatures of yttrium-doped ceria, with different grain sizes and doping concentrations, are determined by electrochemical impedance spectroscopy (EIS). The solid oxide is deposited by reactive magnetron sputtering, which allows modifying the morphology and composition in a controlled way [1]. Improved electrode geometry is also studied. The geometry of an interdigitated electrode structure is designed by 2D simulations for the solid oxide film in contact with the substrate. The spectra recorded with this structure are compared with those measured with two coplanar stripe electrodes.

The impedance modeling with equivalent circuits are performed using a fitting algorithm that provides a quantitative, statistically founded description of the electrochemical system [2-3]. However, our investigation goes beyond the classical EIS analysis. A finite element model (FEM) of the electrical conductivity has been recently developed to simulate impedance spectra and electrical conductivities as a function of grain size and temperature [4]. It is based on the application of the linear phenomenological relations to a crystal lattice. The comparison of the performance of both modeling alternatives will demonstrate the strength of the FEM to adequately explain ion conductivity in nanocrystalline solid oxides.

The presented analysis aims to elucidate the experimental evidence that is not explained by the available physical models. The unique combination of advanced modeling and complete experimental approaches represents a valuable contribution to understand the electrical properties and ion conduction of solid electrolytes.

# Ni/YSZ Electrodes Optimized for Stability at High Electrolysis Current Density

Anne Hauch, Karen Brodersen, Peter S. Jørgensen and Ming Chen  
 Department of Energy Conversion and Storage, Technical University of Denmark  
 DTU Risø Campus, Frederiksborgvej 399, DK-4000 Roskilde, Denmark  
[hauc@dtu.dk](mailto:hauc@dtu.dk)

Cermet Ni/YSZ electrodes are by far the most often applied fuel electrode for solid oxide electrolysis cells (SOEC) and promising results have been shown as reviewed recently[1]. Tietz and co-workers showed promising long-term stability for such SOEC with a degradation rate of  $\sim 3\%$ /kh at high current density ( $-1\text{ A/cm}^2$ ) and high  $p(\text{H}_2\text{O})$ ; however it has been suggested that the long-term degradation rate has to be decreased to a few tens of a percent/kh for the SOEC technology to reach commercial breakthrough [2]. Previous work has shown that the Ni-network is not stable during long-term steam electrolysis at high currents e.g. due to Ni coarsening [2] and Ni migration away from the innermost few microns of the electrode [3][4].

In this work we focus on optimization of the Ni/YSZ electrode structure to ensure long-term stability at high current density ( $-1\text{ A/cm}^2$ ), high steam conversion rate and inlet  $p(\text{H}_2\text{O}) = 0.9\text{ atm}$ . After the initial degradation within the first 1 kh a linear long-term degradation rate of only  $0.3\text{--}0.4\%$ /kh was obtained at  $-1\text{ A/cm}^2$  and  $800\text{ }^\circ\text{C}$ . The increased long-term stability is shown in the figure where long-term test at  $-1\text{ A/cm}^2$  and  $800\text{ }^\circ\text{C}$  for a S-o-A SOEC (Cell 1) is compared with a cell (Cell 2) in which the optimized Ni/YSZ micro-structured electrode was applied. The figure shows cell voltages, polarization resistances ( $R_p$ ) and ohmic resistances ( $R_s$ ) over time during SOEC test at identical test conditions for the two cells. The increased performance and durability originates from a Ni/YSZ structure that has been optimized with respect to porosity, particle sizes, matching of particle sizes including pore sizes and phase percolation. The microstructural characteristics of the optimized Ni/YSZ electrodes have been investigated and quantified using SEM imaging, image analysis and 3D reconstructions; and the microstructural characteristics of Cell 1 and Cell 2 are compared and discussed in view of the electrochemical performance and durability obtained for the two cells.

# Development of Composite Electrolyte Membranes for Polymer Electrolyte Fuel cells Operating at Low Humidity

Sangaraju Shanmugam\* and Kriangsak Ketpang

*Department of Energy Systems Engineering, Daegu Gyeongbuk Institute of Science & Technology, 50-1, Sang-Ri, Hyeonpung-Myeon, Dalseong-Gun, Daegu, Republic of Korea, 711-873; sangarajus@dgist.ac.kr*

Polymer electrolyte fuel cells (PEFC) operated at elevated temperature and low relative humidity (RH) have been attracted considerable attention due to improving electrode kinetics, enhancing anode resistance to CO poisoning, and simplifying thermal management of the system [1]. However, the current PEFC technology, utilizes perfluorosulfonic acid (PFSA) polymer membranes, e.g., Nafion, as electrolyte, exhibits poor performance at elevated temperature and low RH. The deterioration of PEMFC performance at elevated temperature and low RH is mainly attributed to the loss of proton conductivity [2]. Operating PEFC at elevated temperature and low RH lead to membrane dehydration which dramatically reduces the proton conductivity. Thus, it is highly desirable to enhance proton conductivity Nafion membrane at elevated temperature and low RH in order to achieve high PEFC performance at elevated temperature and low RH.

In this presentation, I will discuss the PEFC operated at elevated temperature and low relative humidity by creating additional proton transport channels in a perfluorosulfonic acid membrane using metal oxide nanotubes, graphene inorganic clusters. The performance of composite membranes was evaluated by making MEA and subsequently the composite membranes were investigated the  $H_2/O_2$  fuel cell at 100 °C under 100 %RH and at 80 °C under 18 %RH.  $ZrO_2$  composite membrane operated at 100 °C has 1.6 times higher than commercial membrane (NRE-212) and recast Nafion membrane. On the other hand, the Nafion- $ZrO_2$  composite membrane delivered maximum power density of  $440 \text{ mW cm}^{-2}$ , which is 3 times higher than that of the performance obtained from NRE-212 and recast Nafion membranes [3]. The higher PEFC performance at 100 °C and low RH was due to the hygroscopic property of metal oxide, which can retain water at 100 °C and due to the tubular morphology which facilitates the proton transport channel through membrane.

**Fig. 1.** Polarization curves of various composites membrane operated at 80 °C under 18% RH.

# Fabrication of platinum electrodes with high roughness factor using a 3D-support

M. Frei<sup>1</sup>, J. Erben<sup>1</sup> and S. Kerzenmacher<sup>1</sup>

<sup>1</sup>Laboratory for MEMS Applications,

IMTEK – Department of Microsystems Engineering, University of Freiburg,  
Georges-Koehler-Allee 103, 79110 Freiburg, Germany  
kerzenma@imtek.de

Implantable glucose fuel cells are promising for the sustainable power supply of medical implants. Theoretically, they can generate sufficient electricity to power medical implants such as cardiac pacemakers [1] from electrochemical oxidation of the body's own glucose. However, endogenous substances such as, for instance amino acids, dramatically diminish the performance of the anodes by blocking the catalytic sites [1]. Hence, to enhance the long-time performance high specific surface areas have to be achieved. Our aim is to show that by increasing the roughness factor of the anode (RF; ratio of surface area to geometrical area) and, thus, obtaining more catalytically active sites, higher current densities can be sustained. The state-of-the-art electrodes are fabricated by electro deposition in a Pt-Cu-electrolyte using a flat layer of evaporated platinum as substrate, resulting in electrode RFs of  $6500 \pm 700$  [2]. By using an electro spun carbon as substrate, that in our case already offers a RF of 173 by itself for the platinum deposition, significantly higher RFs should be achievable. In theory, a 173 times higher RF may be achieved if the platinum deposition process can be transferred to the 3-dimensional substrate.

The new electrodes were deposited onto electro spun carbon fiber mats [3] using the established pulsed electro deposition process [2]. So far, 20, 40, 80, 120 and 240 pulses have been applied with 1000 s of waiting time in open circuit potential (OCP) in between the pulses to ensure that fresh electrolyte is available throughout all parts of the porous substrate. To date, this results in electrodes with RFs of about 3900, 5800, 9400, 12600 and 17300 respectively.

To compare the structure of the deposited platinum on the electro spun substrate to the state-of-the-art electrodes, pictures have been taken with a scanning electron microscope (Fig.1, C and D). A and B of figure 1 show the cauliflower-like structure of the porous platinum deposited on the flat substrate [2] for comparison. In figure 1C, the transition from platinum-deposited (right) and non-platinum-deposited (left) electro spun substrate is shown. The deposited platinum already exhibits the same cauliflower-like structure (Fig. 1C) as state-of-the-art electrodes, even though only 20 pulses have been applied to the system compared to the 1200 pulses of the state-of-the-art process [2]. The approximate mean distance of the deposited fibers is  $(610 \pm 260)$  nm, whereas their diameter only reaches  $(240 \pm 74)$  nm leaving a pore size of about 400 nm. Therefore, the pores of the electro spun substrate are wide enough to make more platinum deposition feasible without clogging becoming a problem.

In conclusion, electrodeposition of platinum on electro spun carbon fiber mats is a promising strategy to increase the roughness factor of the anodes for the implantable glucose fuel cell. In future experiments, we will further increase the RF and test the performance of the electrodes in simulated tissue fluids.

The greatest advantages of electrospinning is the possibility of generating composite networks from a rich variety of materials with the ability to control composition, morphology and secondary structure which allows design of optimum material characteristics for variable applications. We used this simple and versatile method to design 3D polymer nanofiber membranes and ceramic metal oxide nanofiber catalysts for green technology with significant improvement in electrochemical performance.

In this talk, we will present several projects that address the sizable challenges in electrochemical devices by electrospinning: 1) electrolyte/catalysts composite electrodes for proton exchange membrane fuel cells; 2) Ceramic nanofiber cathode for solid oxide fuel cells, and 3)  $\text{TiO}_2$  nanofibers catalysts doped with  $\text{WO}_3$  and  $\text{V}_2\text{O}_5$  for deNO<sub>x</sub> in flue gas purification system. The morphology, crystalline structures and composition of nanofibers are intensively studied by SEM, TEM, XRD, BET and elemental analysis. The outcomes of these unique nanofibrous structures are significant improvements in catalytical performance and durability. This brings fuel cell technology and deNO<sub>x</sub> system one step forward toward green technology in real life.

\*mumeda@vos.nagaokaut.ac.jp

For the power generation of polymer electrolyte fuel cells (PEFCs), hydrogen gas including reformed gas is fueled to the fuel cell anode. The reformed hydrogen gas contains a small amount of carbon oxide and 10-30% carbon dioxide [1]. The carbon dioxide is reported to be reduced at Pt electrode [1]. And, a Pt-Ru/C-based membrane electrode assembly (MEA) can reduce it at 0.06-0.3 V vs. DHE [2,3]. However, the reactivity of the carbon dioxide and the reductant adsorption, which both influence the hydrogen oxidation reaction, are not adequately understood. In this study, the reactivity of carbon dioxide and adsorption state of the reductant were investigated using the PEFC containing the Pt-Ru/C-based MEA.

Nafion 117 and Nafion 112 membranes were used as a polymer electrolyte membrane. Electrocatalysts of Pt/C (Pt: 45.7 wt.%), Pt-Ru/C (Pt:Ru=32.6:16.9 wt.% (molar ratio: Pt:Ru=1:1), and Pt:Ru=29.5:22.9 wt.% (molar ratio: Pt:Ru=2:3)) were sprayed on gas diffusion layers. The electrolyte membrane was sandwiched by two pieces of the gas diffusion layers which were coated electrocatalysts layers (metal amount: 1.0 mg cm<sup>-2</sup>), and then hot-pressed. Thus, the desired MEA was obtained. Geometric electrode area of the MEA was 3 × 3 cm<sup>2</sup>. The MEA has a Pt-Ru/C as a working electrode and a Pt/C as a counter electrode. The prepared MEA was installed in a single cell having a dynamic hydrogen electrode (DHE) as a reference electrode. The temperature of the single cell was controlled at 40, 60, 80, 90, and 95°C. Humidified carbon dioxide gas (purity: 99.995%) and humidified hydrogen gas (purity: 99.999%) were supplied to the working and counter electrode, respectively, at the flow rate of 50 cm<sup>3</sup> min<sup>-1</sup> by a PEFC power generation unit. Cyclic voltammograms were measured at a potential scan rate of 10 mV s<sup>-1</sup> and the potential scan range was settled to be 0.06–0.70 V vs. DHE. For comparison, Pt/C electrocatalyst was also used as the working electrode.

To investigate the anode performance of the Pt-Ru/C-based MEA in a single cell equipped with a reference electrode (DHE) under carbon dioxide atmosphere. Figure 1 shows the cyclic voltammograms of Pt/C and Pt-Ru/C (Pt:Ru=1:1 or 2:3) MEAs at 95°C cell temperature under nitrogen and carbon dioxide atmospheres. When it was swept toward the positive direction, the current density peaks are observed at around 0.2-0.6 V vs. DHE in all graphs in Fig. 1. These peaks are known to be re-oxidation peaks of the carbon dioxide reductant. The arrows show onset potentials at each electrocatalysts. The onset potential of re-oxidation peak at Pt/C is much positive than that at Pt-Ru/C electrocatalysts. The Pt-Ru/C (Pt:Ru=2:3) shifts toward negative direction in the electrocatalysts. It is considered that the Pt to Ru ratio in Pt-Ru/C affects the re-oxidation of carbon dioxide reductant and its desorption process.

# A DEMS Study on the Influence of Ag Add-Atoms on Pd-based Catalysts for Methanol Oxidation in Alkaline Environment

Tilman Jurzinsky, Carsten Cremers, Karsten Pinkwart, Jens Tübke  
Fraunhofer Institute for Chemical Technology ICT  
Joseph-von-Fraunhofer-Str. 7, 76327 Pfaffzettel, Germany  
tilman.jurzinsky@ict.fraunhofer.de

In the last decades, the enhancement of anion-exchange membranes (AEMs) took big steps regarding the stability in alkaline environment while having proper ion exchange capacities and ionic conductivities. Due to this development, it is possible to use AEMs in direct alcohol fuel cells (DAFCs) making them anion-exchange membrane direct alcohol fuel cells (AEM-DAFCs). By changing the pH conditions of the fuel cell from acidic to alkaline, electrode reaction kinetics are positively influenced and platinum-free catalysts are feasible for alcohol oxidation reaction (AOR) and oxygen reduction reaction (ORR). While for ORR metals and oxides like Ag and  $\text{MnO}_2$  are promising catalysts, for AOR promising catalysts are Pd-based catalysts like PdAg/C and PdNi/C.

Complete oxidation of methanol into  $\text{CO}_2$  is essential for an efficient energy production. From the literature it is known that besides  $\text{CO}_2$  there are two more side products occurring during methanol oxidation in alkaline media: formaldehyde and formic acid. As there are fewer electrons exchanged during formation of these side products, the production of formaldehyde and formic acid during methanol oxidation reaction (MOR) is equivalent to a loss of faradaic current compared to a complete oxidation of methanol to  $\text{CO}_2$ . That is why it is crucial to investigate on catalysts which are able to reach high  $\text{CO}_2$  current efficiencies (CCE).

To further understand the influence of add-metals on Pd and the resulting gain in electrolytic activity, this study aims for a deeper understanding of the methanol electro-oxidation mechanism on Pd-based bimetallic catalysts. Differential electrochemical mass spectrometry (DEMS) is a powerful tool to investigate the product distribution during methanol electro-oxidation and  $\text{CO}_2$  current efficiency. Besides this, it is possible to identify poisoning species on the catalysts during MOR by methanol stripping experiments in DEMS setup giving a hint on the stability of the catalysts in fuel cell operation.

In a former study, we reported on the catalytic activity of PdAg/C catalysts for MOR in alkaline media.[1] Based on these findings, we

further investigated on the poisoning behavior, CCE and product distribution of Pd/C, Ag/C and PdAg/C via cyclic voltammetry, CO stripping and methanol stripping experiments in a DEMS flow cell setup.

Figure 1 shows the patterns derived from cyclic voltammetry for different catalysts in a 0.1M  $\text{CH}_3\text{OH}$  + 0.5M KOH solution in the DEMS flow cell with a Pt-electrode and a reversible hydrogen electrode (RHE) as counter- and reference-electrode, respectively. For comparison a Pt/C (Hi-SPEC3000) catalyst was also investigated as a reference material. Besides a higher CCE value for bimetallic Pd-based catalysts it could also be shown by methanol stripping experiments that catalyst poisoning is less for Ag containing Pd-based catalysts than for plain Pd/C or Pt/C.

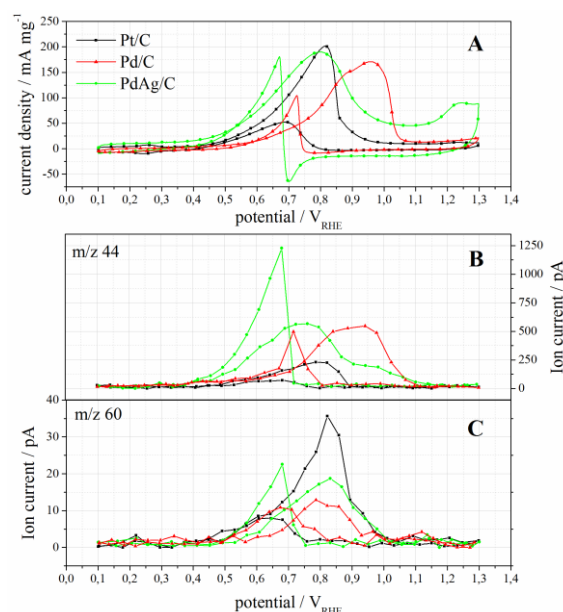

Figure 1: CV plots (A) of Pt/C, Pd/C and PdAg/C in 0.1M  $\text{CH}_3\text{OH}$  + 0.5M KOH in a DEMS flow cell and corresponding MS signals for  $\text{CO}_2$  (B) and methyl ester of formic acid (C).

## Background

Development of non-platinum group metals cathodes is required for practical application of polymer electrolyte fuel cells. We focused on group 4 and 5 metal oxide-based compounds because their high chemical stabilities in acidic media. We attempted to enhance the activity of the oxygen reduction reaction (ORR) to prepare nano-sized oxide-particles by use of metal organic complexes such as oxy-metal phthalocyanines as precursors with multi-walled carbon nanotubes as supports<sup>1</sup>. Although the ORR activities drastically increased, the stabilities of these catalysts were low because the deposited carbon derived from phthalocyanines degraded under cathode conditions. Therefore, in order to achieve both high ORR activity and high durability, we need to develop the oxide-based cathodes without carbon materials.

## Catalyst design of non-platinum group metals and carbon-free cathodes

To prepare the non-precious metal and carbon-free cathodes, the basic idea is a combination of electro-conductive oxides and oxides with active sites for the ORR. We focused on titanium oxide, Ti<sub>4</sub>O<sub>7</sub>, known as magneli phase, as electrical conductive. On the other hand, titanium-niobium complex oxides (Nb-doped TiO<sub>2</sub>) were applied to create the active sites. The strategy of the preparation of the Ti-Nb complex oxides and Ti<sub>4</sub>O<sub>7</sub> was a dry ball-milling and a reductive heat-treatment in this study. We performed start-stop cycle test (triangular wave, 1.0 - 1.5 V vs. reversible hydrogen electrode (RHE), N<sub>2</sub>, a scan rate: 0.5 V s<sup>-1</sup>) and load cycle test (rectangular wave, 0.6 - 1.0 V vs. RHE, O<sub>2</sub>, holding time: 3 s) were performed as degradation tests using a 3-electrode cell in 0.1 M H<sub>2</sub>SO<sub>4</sub> at 30 °C.

## Demonstration of high durability

Figures 1 (a) and (b) show the dependence of the ratio of the ORR current obtained by chronoamperometry at 0.7 V at the beginning and during the start-stop cycle test,  $N_{iCA@0.7V}$ , and Dependence of  $N_{iCA@0.65V}$  at the beginning and during the load cycle test. Surprisingly, in both cases the  $N_{iCA@0.7V}$  and  $N_{iCA@0.65V}$  increased until 5000 cycles, and they became nearly constant over 5000 until 20000 cycles. These results demonstrated that the all oxide-based (carbon-free) cathodes had high durability in both high and low potential regions.

In recent years, due to high electrical conductivity, formability, manufacturability, gas impermeability and superior mechanical properties, metallic bipolar plates such as stainless steel are used to connect the polymer electrolyte fuel cell (PEFC) in series. However, one big problem of the bipolar plate is the corrosion in the actual cell environment [1]. The purpose of the present study is to evaluate the corrosion behaviors of Ni-free nitriding SUS445N stainless steels with different treatment conditions of temperature and time by a linear sweep voltammetry measurement. The nitriding stainless steel has been reported to have high resistance and good electrical conductivity [2]. Non-treatment stainless steel SUS445 was used for comparison.

The Ni-free nitriding stainless steels used in this study were the SUS445N stainless steels heat treated under the nitrogen gas atmosphere at 1150 and 1200° C for 2 h. In order to analyze the corrosion characteristics of the SUS445N stainless steel, a corrosion test was conducted in a schale electrochemical cell with a platinum coil counter electrode, an Ag/Ag<sub>2</sub>SO<sub>4</sub> reference electrode, and the SUS445N stainless steel as the working electrode. The electrolyte was 0.5 mol dm<sup>-3</sup> H<sub>2</sub>SO<sub>4</sub> solution. Before the liner sweep voltammetry (LSV) measurement, the stainless steels were washed with distilled water and acetone for 5 min in sonication and then 30 min Ar gas bubbling was conducted. Subsequently, the cathodic treatment was carried out under the potential of -0.47 V vs. SHE for 1 min and then kept the cell under the rest potential for 5 min. During this step, the invisible H<sub>2</sub> gas generated on the surface of the sample was removed by Ar bubble. For the electrochemical test, the potential was scanned from the rest potential to 1.1 V vs. SHE at a scan rate of 0.33 mV s<sup>-1</sup>.

Figure 1 shows liner sweep voltammograms of SUS445 and SUS445N stainless steel in Ar-saturated 0.5 mol dm<sup>-3</sup> H<sub>2</sub>SO<sub>4</sub> solution at room temperature. The SUS445N stainless steels were heat treated at 1150°C and 1200°C for 2 hours, respectively. The anodic current densities in passive region of SUS445N (1200°C) sample are about one order of magnitude lower than those for the SUS445N (1150°C) specimen. And the passive region current densities of SUS445N (1150°C) sample are almost the same as non-treatment stainless steel. That means the SUS445N stainless steel heat treated at 1200° C has a higher resistance to corrosion than that heat treated at 1150°C. The polarization curve of SUS445N (1150°C) sample has the current peak that forms passive layer at about -0.2 V vs. SHE. However, there is no current peak for SUS445N (1200°C) sample. It is found that the treat temperature plays an important role of improving the corrosion resistant of nitriding SUS445N stainless steel. From the results of GD-OES, the improvement of the corrosion resistance can be explained by the N, Al and Cr components on the surface of the nitriding stainless steel.

Fig. 1 Polarization curves of SUS445, SUS445N (1150°C) and SUS445N (1200°C) stainless steels in Ar-saturated 0.5 mol dm<sup>-3</sup> H<sub>2</sub>SO<sub>4</sub> solution at room temperature. Scan rate: 0.33 mV s<sup>-1</sup>.

Liquid fuel cells are a kind of electrochemical energy convertor with borohydride aqueous solution or light hydrocarbons as fuel. They are with merits of high efficiency, low environmental impact as well as circumventing the problem of hydrogen storage in  $H_2/O_2$  fuel cells. The main challenges of the liquid fuel cells are the fuel crossover and sluggish kinetics of oxygen reduction reaction (ORR). Ion exchange membrane (IEM) is a very important component in traditional liquid fuel cells. It is used to screen ion transport and limit the fuel crossover. However, IEMs have poor performance in limiting fuel crossover in the actual working conditions. The fuel crossover through the IEM and then poisoning the cathodic catalysts greatly decrease the performance of liquid fuel cells. In addition, the high cost of both IEM and noble metal catalysts limits the commercialization of the liquid fuel cells.

In this work, we presented a high active and durable Fe/N/C catalyst for ORR by employing 2-aminothiazole (2-AT) as precursor that contains both N and S elements. Excellent activity and fuel-tolerance has been observed. The excellent fuel-tolerance helps to circumvent the fuel crossover problem in liquid fuel cells. By employing the Fe/N/C catalyst, a polymer fiber membrane (PFM) was introduced in liquid fuel cells to replace IEM<sup>[1]</sup>. The PFM is in a non-woven structure and acts as a thin liquid electrolyte layer in liquid fuel cells. All ions can transport freely in the PFM. As a consequence, the resistance between electrodes was greatly reduced. At the same time, the price of PFM is much lower compared with IEM. The performances of liquid fuel cells were improved greatly when PFM was used in direct borohydride fuel cell (DBFC)<sup>[1]</sup> and direct methanol fuel cell (DMFC)<sup>[2]</sup>.

Figure. a) Illustration of liquid fuel cells using porous polypropylene fiber separator as membrane. Fuel (borohydride or methanol) can cross over freely through this permeable membrane, so cathode catalyst should be resistant to methanol. b) The power output was improved because of the low resistance with porous porous polypropylene fiber membrane.

*E-mail: [hujis@iccas.ac.cn](mailto:hujis@iccas.ac.cn)*

The rapidly increasing energy demand for human activities stimulates the lasting research interests to develop renewable energy alternatives worldwide. Fuel cell, as a clean and efficient energy conversion device, is one of promising techniques in tackling future global energy crisis. The big challenges for the practical application of this technique are to minimize the use and maximize the catalytic activity of scarce, expensive but still best platinum-based catalysts, and tackle the issue of the sluggish cathode oxygen reduction reaction (ORR).<sup>1,2</sup>

In this presentation, several reasonable ways for designing new nanocatalysts with high electrocatalytic activities and superior stability for ORR will be discussed. For example, 1) By improving the structures of Pt-based catalysts and harnessing the synergetic catalytic effect from support, a series of nanocatalysts with efficient usage of Pt component and enhanced electrocatalytic performance were developed, including Pt nanocrystal assembled hollow Pt nanostructures hanged onto graphene layer,<sup>3</sup> well-dispersed Pt nanocrystals on Mn<sub>3</sub>O<sub>4</sub> coated CNTs prepared via an in-situ self-deposition process,<sup>4</sup> and CNx/CNTs embedded with Pt nanocrystals for improving stability,<sup>5</sup> etc. 2) For further minimizing the catalyst cost, a variety of non-PGM (platinum group metal) catalysts with comparable/superior electrochemical performance and durability were developed, such as in-situ nitrogen-doped nanoporous carbon nanocables,<sup>6</sup> improved graphene/carbon nanotube composites,<sup>7</sup> and selectively-nitrogen-doped graphene via space confinement etc.<sup>8</sup> 3) The further improvement of the performance can be achieved by introducing transition metal or nanostructures into these nanocatalysts.<sup>9,10</sup> 4) A molten salt-assisted strategy was also developed to synthesize a new type of nanoporous nitrogen-doped carbon materials, which exhibited superior electrocatalytic activity for ORR even better than commercial Pt/C.<sup>11</sup> 5) Lastly, A simple, reproducible and cost-effective protocol to produce a nanocomposite from graphene supported layered double hydroxide will be also discussed, which will be interesting for cost-effective mass production of electrocatalysts for industrial applications.<sup>12</sup>

# **Review of the Latest Advances and Current Challenges of Anion Exchange Membrane Fuel Cell Technology**

Dario R. Dekel

*Technion – Israel Institute of Technology  
Technion City, Haifa, 32000 Israel  
dario@technion.ac.il*

The alkaline Anion Exchange Membrane Fuel Cell (AEM-FC) is a new and blooming technology. It keeps the advantages of the solid polymer electrolyte membrane based fuel cell, and due to its alkaline polymer medium it provides a real opportunity to replace the Pt electrocatalysts and therefore to solve the major cost barriers of the mainstream proton exchange membrane fuel cell (PEM-FC) technology. AEM-FCs have been rapidly developed for the past five years, and for the first time there are tens of research groups developing unique AEMs with outstanding properties as well as first groups developing non-Pt electrocatalysts for oxidation reduction reaction (ORR) replacing finally the expensive Pt based electrodes used in PEM-FC cathodes.

In spite of this impressive and rapid development, AEM-FCs are still far from reaching a practical use, and still major advances are required. Among present challenges that should be now overcome are: development of highly active non-Pt electrocatalysts for hydrogen oxidation reaction (HOR), AEMs with higher immunity to CO<sub>2</sub>, and stable anion conductive functional groups able to withstand higher temperatures at low relative humidity. To recognize AEM-FC as a real future technology, all those development challenges must be addressed without exception. Advances in developments in those three specific fields will facilitate rapid acceptance of AEM-FC technology and allow development of first affordable fuel cell products.

In this talk, the latest advances in the technology and critical insights of current challenges will be presented.

# Well-ordered Ru@Pt Core-shell Nanocatalysts with Tunable Composition and Enhanced Electrocatalytic Properties

Jianguo Liu\*, Jin Xie, Zhigang Zou

College of Engineering and Applied Sciences, Nanjing University, Nanjing 210093, China, Email :  
jianguoliu@nju.edu.cn

Among various kinds of fuel cells, direct methanol fuel cells (DMFCs) have been attracting significant interest and research efforts for its great potential to be commercialized as the major power source for portable electric devices, due to the facile storage and refilling characteristics of methanol fuel. However, two critical issues have to be confronted when designing an effective methanol oxidation electrocatalysts: catalysts poisoning and dissolution. Alloying Pt with other metals, such as Ru, Pd, Au and so forth, has been extensively investigated to improve CO tolerance and catalytic activity of the MOR catalysts. Among them, Pt-Ru alloy was shown to have the best overall performance, which was traditionally attributed to a bi-functional mechanism or ligand effect. However, ruthenium dissolution remains the major reason for the invalidation of fuel cells, especially at high potentials experienced during startup and shutdown [1-3]. Compared to PtRu alloy nanocatalysts, Ru (core)-Pt (shell) catalysts are highly promising for DMFCs.

Ru@Pt NPs synthesized by polyalcohol method were reported to have enhanced methanol oxidation activity. However, in these studies, Ru cores often existed in a disordered state. And Pt atoms tend to diffuse into the disordered Ru cores through defects. Therefore, alloying was often obtained instead of uniform Pt shell formation. Hsieh and co-workers reported a green synthesis route to well-ordered Ru@Pt NPs that showed superior durability and excellent CO tolerance for hydrogen oxidation reaction [4]. We developed a microwave reaction technique that allowed the use of ethanol as an eco-friendly reductant and solvent under relatively mild conditions. The as-produced Ru@Pt catalysts show a higher methanol oxidation activity and CO-deactivation resistance than the commercial Pt-Ru catalysts. Meanwhile, they also exhibit substantial durability upon long term potential cycling. Fig. 1 shows the cyclic voltammetry, fuel cell tests, XRD, and TEM images of JM-PtRu/C and Ru@Pt0.5/C.

Our results indicate that ordered thin-layer core-shell Ru@Pt can not only enhance the catalytic properties, but also efficiently protect ruthenium from dissolution. This type of core-shell catalysts will be potential for solving the dilemma of long term durability in DMFCs anodes.

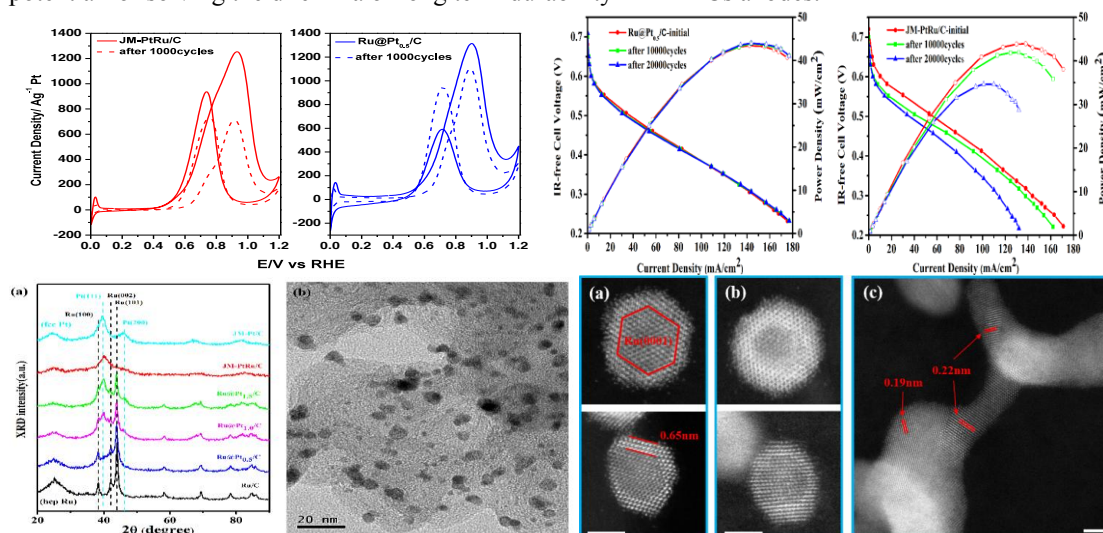

Figure 1. Catalytic activity, stability, XRD, and TEM images of JM-PtRu/C and Ru@Pt0.5/C. Cyclic voltammograms of JM-PtRu/C, Ru@Pt0.5/C in 1M CH<sub>3</sub>OH (up), IV Curves and Power density of JM-PtRu/C, Ru@Pt0.5/C in Fuel Cell.

Nanocarbon materials are of great importance in electrochemical energy storage and conversion systems, including lithium ion batteries, electrochemical capacitors and polymer electrolyte fuel cells. Our research group has reported the template-assisted synthesis of carbon nanofibers by liquid phase carbonization of polymers (1-3). The resultant carbon nanofibers have unique orientation of carbon layers, and platelet-type carbon nanofibers (p-CNFs) with hexagonal carbon layers stacked to the fiber axis are developed. Since the edge planes of hexagonal carbon layers are exposed at the most of p-CNFs surface. Here, we report the uniform deposition of Pt nanoparticles on the p-CNFs and the high activity and durability of the Pt/p-CNFs electrodes for oxygen reduction reaction (ORR).

Porous anodic alumina films with cylindrical pores of ~50 nm pore diameter were used as template. The p-CNFs were prepared by heating a mixture of the template and polyvinyl chloride powders in high purity argon atmosphere to 600°C. p-CNFs were further heat-treated at higher temperatures up to 1400°C to control the graphitization degree. Pt deposition was carried out using dinitro-diamine platinum(II) and ethanol as a reductant. Pt nanoparticles were also deposited on commercial Ketjen black (KB) for comparison. Electrochemical measurements were carried out by using rotating disk electrode with normal three electrode system. Pt wire and Ag/AgCl was used as a counter electrode and reference electrode, respectively. The electrolyte used was 0.05 M sulphuric acid.

The Pt nanoparticles of approximately 3 nm were homogeneously deposited on the p-CNFs, rather than on KB. The homogeneity was improved on the p-CNFs heat-treated at higher temperatures, probably since more reactive edges of hexagonal carbon layers were exposed after heat treatment at higher temperatures. The electrochemical activity per Pt surface area became higher on the Pt/p-CNFs that heat treatment of p-CNFs was conducted at higher temperatures. Remarkable durability enhancement was also found when we used the p-CNFs heat-treated at 1400°C. After potential cycles of 200 between 0.5 V and 1.5 V, Pt/p-CNF (1500°C) shows only less than 10% reduction of the ORR activity, whereas the activity reduction was as high as ~90% for the Pt/KB. The p-CNFs are promising carbon support for ORR electrocatalysts with high activity and durability.

# **Solid Oxide Fuel Cells - A Clean and Efficient Energy Technology for the Future**

Nguyen Q. Minh  
*Center for Energy Research*  
*University of California, San Diego*  
*9500 Gilman Drive, La Jolla, CA 92093-0417, USA*  
*nminh@ucsd.edu*

Solid oxide fuel cell (SOFC) technology has received attention in the past 20 years as a clean and efficient energy conversion technology for a variety of practical fuels. The attractive features of the technology include cell and stack design flexibility, multiple cell fabrication options, multifuel and multifunctional capacity and operating temperature choices. The SOFC has been under development for a broad spectrum of power generation applications. Many of the applications have progressed to hardware demonstration and prototype/precommercial stages, especially those with power outputs of 200 kW or less. Significant advancements have been made in several technological areas critical to the development and commercialization of the fuel cell: performance, fabrication scaleup and miniaturization, fuel utilization and performance degradation and durability. The SOFC can also operate in reverse (electrolysis) mode (referred to as solid oxide electrolysis cell or SOEC) and has been considered for hydrogen/oxygen production from steam and syngas from mixtures of steam and carbon dioxide. This paper summarizes and discusses the development status and recent progresses in the development of the SOFC for power generation and hydrogen/chemical production.

# Ion Exchange Polymer Threaded in MOF as a Potential Electrolyte with Fast Exchange and High Selectivity

Kwong-Yu Chan, Liang Gao, Chi-Ying Vanessa Li  
Department of Chemistry, The University of Hong Kong  
Pokfulam Road, Hong Kong  
hrsccy@hku.hk

The high porosity, high surface area and uniform ordered structure of metal organic frameworks (MOFs) have been explored in board applications. Inspired by Kitigawa and co-workers [1], we extend the concept of “*in situ* polymerization in MOF” to include polymers functionalized to provide ion-exchangeable sites. We report a porous metal-organic framework composite with flexible anion-exchange polymers threaded within the host cavity. [2] Polyvinyl benzyl trimethylammonium hydroxide (PVBTAH) threaded in ZIF-8 (PVBTAH~ZIF-8) (Fig. 1) is synthesized in steps of chloro-monomer impregnation, *in situ* polymerization, amination, and alkaline ion exchange. The synthesized non-cross-linked PVBTAH~ZIF-8 material exhibits superior ion-exchange kinetics compared to conventional ion-exchange resins (Fig. 2). The open porous structure of MOF allows the physically trapped polymers to contact solvent freely and exchange ions efficiently, as oppose to the conventional ion-exchange resins in which the binding sites are hidden within the polymeric beads, preventing full utilization of ion exchange sites. It has good potential to be applied as a hybrid polymeric electrolyte in advanced fuel cells and flow batteries which demands high ionic selectivity.

**Fig. 1** Schematic illustration of the PVBTAH anion exchange polymer in MOF ZIF-8.

**Figure 2.**  $\text{Au}(\text{CN})_2^-$  concentration after immersing equal masses of PVBTAH~ZIF-8 and Amberlyst-A26 in  $\text{KAu}(\text{CN})_2$  solution. Inset shows enlarged profiles of the first 120 seconds.

# RDE system for ORR measurements at elevated (>100 C) temperature and pressure conditions

Michael Fleige, Gustav K.H. Wiberg, and Matthias Arenz  
*Department of Chemistry and Nano-Science Center, University of Copenhagen  
Universitetsparken 5, 2100 Ø Copenhagen, Denmark*

*m.fleige@chem.ku.dk*

**Abstract.** Rotating disk electrodes (RDE) are widely used for mimicking conditions in polymer electrolyte fuel cells (PEMFCs), for example for ex situ measurements of the catalytic activity of fuel cell catalysts. However, using RDE current densities are much lower compared to fuel cells, as in liquid electrolyte mass transport of dissolved reactant gases is limited by orders of magnitude lower concentrations and diffusion coefficients compared to gas phase. Furthermore, owing greatly reduced gas solubility by increasing vapor pressure of water at elevated temperatures, RDE studies in open systems have been limited to about 60 C.<sup>1</sup> Employing RDE at elevated pressure would allow increasing reactant gas solubility and raising the boiling point of water. In addition, conc. phosphoric acid (PA), which is typically not considered in RDE studies due its even lower gas solubility, could be used for RDE measurements at sufficient gas concentration.

This presentation will discuss a developed RDE system that was integrated in an elevated pressure and temperature electrochemical cell setup reported earlier.<sup>2,3</sup> The RDE system is based on a magnet coupled drive, avoiding use of a rotary seal autoclave feed-through as proposed previously.<sup>4</sup>

We tested the magnet coupled RDE up to 100 bar pressure by studying the ORR on polycrystalline Pt as a test reaction in 0.5 M H<sub>2</sub>SO<sub>4</sub> as well as conc. PA electrolyte. By increasing the pressure of oxygen in the closed cell, the diffusion limited current densities can be increased by almost two orders of magnitude in dilute electrolyte and RDE measurements in conc. PA are enabled. The RDE system also was successfully tested at elevated temperatures up to 140 C. Kinetic measurements of the ORR under elevated pressure conditions are currently in preparation.

philipp.lettenmeier@dlr.de

Hydrogen can be used as an energy vector for renewable energies such as solar or wind by using water electrolysis systems [1]. Commercially, it can be electrochemically produced by alkaline and proton exchange membrane (PEM) electrolysis, at which the investment cost of the later is presently almost three times higher than the alkaline technology [2]. However, the main advantage of PEM electrolyzers is the possibility to operate at much higher current densities with a significant potential for cost reduction owing to the compact design [3]. An open question is still the life time of the membrane electrode assembly (MEA) of the PEM electrolyser operating at high performance. In this work rainbow stacks with MEAs from different suppliers are tested in a 20 kW PEM electrolyser ( $2.5 \text{ N m}^3 \text{ H}_2 \text{ h}^{-1}$ ) operating constantly and dynamically up to  $5 \text{ A cm}^{-2}$ . The  $120 \text{ cm}^2$  active area MEAs have membranes with the same thickness but different Ir-based catalyst loadings. The cell voltage ( $E_{\text{cell}}$ ) increases ca. 50 mV at  $1.25 \text{ A cm}^{-2}$  when reducing the anode loading by 30% (Figure 1a), although this parameter does not influence the degradation rate. It is possible to reduce the cell voltage by 150 mV at  $3.3 \text{ A cm}^{-2}$  by increasing the temperature from  $28^\circ$  to  $48^\circ \text{ C}$ . At the maximum current density the stack temperature and  $E_{\text{cell}}$  reach almost  $65^\circ \text{ C}$  and 2.5 V, respectively. Operating the electrolyser at low current densities has an impact in the  $\text{H}_2$  crossover. The most durable MEAs do not experience any lost in performance after more than 3000 h of operation under stationary and dynamic regimes. Post-mortem characterisation and water analysis are carried out to determine the degradation mechanism of the rest of the MEAs.

Fig. 1. Cell voltage and current density characteristics of a  $120 \text{ cm}^2$  stack with half of the cells having anode catalyst loadings of  $2.4 \text{ g cm}^{-2}$  and the other half with  $3.5 \text{ g cm}^{-2}$ . The measurements are performed at 7 bar and two different stack temperatures. The step rate of the rectifier is  $4.2 \text{ mA cm}^{-2} \text{ s}^{-1}$ .

# Amperometric Study of the Oxygen Reduction Reaction on Oxide Free Metals: Evidence for the Reduction of Pre-adsorbed Dioxygen and its Dependence on the Metal Substrate

Guy Denuault, Samuel C. Perry  
University of Southampton  
University Road, Southampton SO17 1BJ, UK  
gd@soton.ac.uk

We present experimental results which provide new insight on the electrochemical reduction of oxygen on oxide free metals. Using chronoamperometry at microdisc electrodes in aqueous media, we investigated the oxygen reduction reaction (ORR) on the millisecond timescale and found an unexpected chronoamperometric response. At long times, the amperometric response follows the theoretical diffusion controlled chronoamperogram at microdiscs<sup>1,2</sup> thereby indicating that the ORR rate is solely controlled by the diffusion of dissolved oxygen towards the microelectrode. However, at short times, typically below 50 ms, the reduction of oxygen produces a large extra current whose magnitude was found to depend on the electrode metal, deliberate electrode poisoning, the oxygen concentration in solution, and the rest time prior to a potential step being performed. Remarkably the extra charge recorded at short times was found to systematically vary with reported theoretical calculations of the binding energy of oxygen with respect to the electrode material,<sup>3</sup> figure 1.

Figure 1: Extra charge calculated from the difference between experimental and theoretical current transients for the oxygen reduction reaction at Ni, Cu, Pt, Ag and Au against the binding energy reported by Norskov et al.<sup>3</sup> for those metals toward oxygen.

Overall the results provide clear experimental evidence for the reduction of oxygen pre-adsorbed on oxide free metals. By taking steps to manipulate the amount of pre-adsorbed oxygen we also show that the extra current can be systematically altered. These results provide not only a new insight into the ORR mechanism but also a new strategy to investigate the properties of ORR catalysts and a clear link between experimental and theoretical data.

# Pt-free Catalyst for Oxygen Reduction Reaction in Fuel Cells

Ding Wei, Li Li, Siguo Chen, Xueqiang Qi, Zidong Wei\*

School of Chemistry and Chemical Engineering, Chongqing University, Shazhengjie 174, Chongqing, 400044, China  
zdwei@cqu.edu.cn

Developing catalytic materials for oxygen reduction reactions (ORR) with high performance and low cost has been one of the major challenges for large-scale applications of fuel cells. The involved scientific issues include theoretical understanding of the catalysis mechanisms, catalyst material design and synthesis, and integration of catalysts into fuel cell operations. Among various catalytic materials,  $sp^2$  carbon materials having abundant free-flowing  $\pi$ -electrons are potential catalysts for the ORR. Breaking the electroneutrality of graphitic materials by doping with heteroatoms to create charged sites favorable for  $O_2$  adsorption is the key factor in enhancing ORR activity, regardless of whether the dopant is electron-rich (e.g. N) or electron-deficient (e.g. P, B).<sup>[1]</sup> As for nitrogen doped carbon catalyst, the molecular structure of nitrogen is a critical role in affecting its catalytic properties. Recently, we presented a strategy for the selective synthesis of pyridinic- and pyrrolic-nitrogen-doped graphene (NG) by the use of layered montmorillonite (MMT) as a quasi-closed flat nanoreactor.<sup>[2]</sup> The confinement effect of MMT extensively constrains the formation of quaternary N because of its tetrahedral  $sp^3$  configuration but facilitates the formation of planar N, i.e. pyridinic and pyrrolic N which have planar  $sp^2$  configuration (fig. 1a). The content of planar N sites was inversely proportional to the interspace width ( $\delta$ ) of the

MMT, and it reached a maximum of 90.27% with the MMT interspace width at 0.46 nm. The planar N doped graphene exhibited a low electrical resistance and high electrocatalytic activity with a half-wave potential of the ORR that lags behind the state-of-the-art carbon-supported platinum by only 60 mV in an acidic electrolyte. As for integration of catalysts into fuel cell operations, the exposure of the active sites to the interface, where electrons, protons, oxygen and product water can flow in or exit out, is particularly important. It would be better if the catalysts are porous enough to accommodate the linkage of various species-transport channels to their active sites: voids for  $O_2$  and water, a polymer chain for protons, and a carbon framework for electrons. At this point, we developed a “shape fixing via salt recrystallization” method to efficiently synthesize nitrogen-doped carbon material with a large number of active sites exposed to the three-phase zones.<sup>[3]</sup> The active sites (activated by planar pyridinic and pyrrolic N atoms with  $sp^2$  hybrid orbitals, which only appear at the outside fringe of a graphene sheet) appear in large quantities on the edges of numerous pores. A three dimensional network catalyst structure with a high density of ORR active sites, which is conducive to mass transport and high utilization of active sites, was constructed (fig. 1b). The cathode catalyst in a proton exchange membrane fuel cell produces a peak power of  $600 \text{ mWcm}^{-2}$ , making this among the best non-precious metal catalysts for the ORR reported so far.

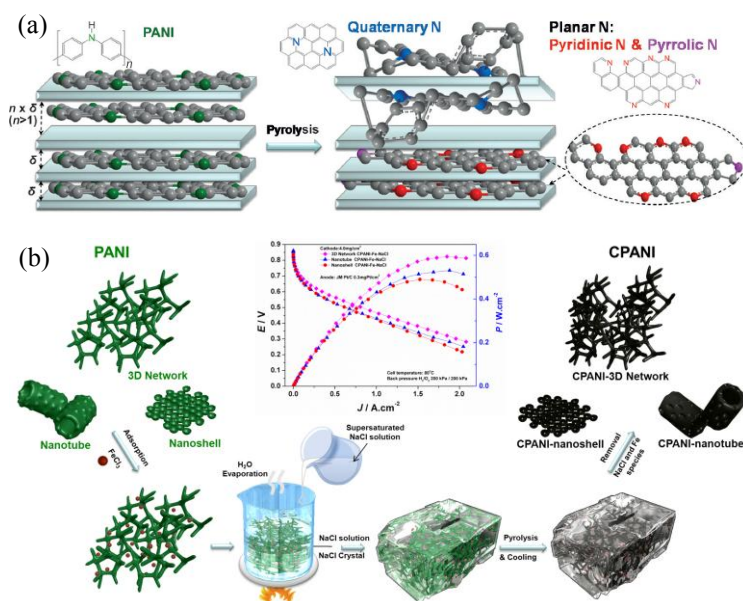

Figure 1. (a) the selective synthesis inside and outside MMT, (b) shape Fixing via Salt Recrystallization Method.

# Preparation of Ni-Co Nanowire Arrays Anode Electrocatalyst and the Performance of Direct Urea-Hydrogen Peroxide Fuel Cell

Fen Guo, Dianxue Cao<sup>\*</sup>, Ke Ye, Kui Cheng, Mengmeng Du, Dongming Zhang

Key Laboratory of Superlight Materials and Surface Technology, Ministry of Education, College of Materials Science and Chemical Engineering, Harbin Engineering University, Harbin, 150001, P.R. China.

E-mail address: caodianxue@hrbeu.edu.cn

Waste water containing Urea is discharged every day in the form of urine or chemical fertilizer factory sewage. Direct urea fuel cell (DUFC) is composed of urea electro-oxidation in the anode and oxygen or hydrogen peroxide electro-reduction in the cathode[1]. The fuel cell can play a dual role by generating electricity and alleviating urea-rich pollutant in one step. Nickel proves to be an effective catalyst for urea electro-oxidation[2]. Studies show that the composition of catalyst would be rather influential on the performance of urea electro-oxidation. In this work, polycarbonate (PC) membrane was used as the template to prepare Ni-Co nanowire arrays (NWAs) electrode. Without ion sputtering or thermal evaporation of metals on the template as conductive film, PC membrane is attached on low melting point alloy, which is re-usable and easy for handling. The electrodeposition keeps running until a layer of Ni-Co substrate is formed even after the pores are completely filled with nickel and cobalt. When the mass ratio of nickel and cobalt salts in the electrodeposition solution was 9:1, the as-prepared Ni-Co NWAs electrode demonstrated best performance for urea electro-oxidation, i.e., a maximum oxidation current density of  $380 \text{ mA cm}^{-2}$  and an onset oxidation potential of  $0.188 \text{ V}$  vs.  $\text{Ag}/\text{AgCl}$  in  $5 \text{ mol L}^{-1}$   $\text{KOH}$  and  $0.33 \text{ mol L}^{-1}$  urea. Importantly, the onset oxidation potential hardly exhibited negative shifts with the increase of cobalt salt content.

Fig.1. The digital photograph and the SEM image of Ni-Co NWAs electrode (inset); Fig.2. The performance of direct urea-hydrogen peroxide fuel cell. Open dots: CFC at both sides, solid dots: Ni-Co NWAs and Pd@CFC respectively.

Fig.1 shows the digital photograph of Ni-Co NWAs electrode. The black side is PC membrane filled with nanowires. The back side is a layer of Ni-Co substrate. The inset is the SEM image of NWAs electrode after dissolving the PC membrane in dichloromethane. The nanowires stand on the Ni-Co substrate and array in line like ears of wheat. Fig.2 displays the performance of direct urea-hydrogen peroxide fuel cell. At the cathode side,  $\text{H}_2\text{O}_2$  is used as the oxidant and Pd@carbon fiber cloth (CFC) acts as cathode catalyst. The anode fuel, urea, is electro-catalyzed by Ni-Co NWAs electrode. The whole cell achieves an open circuit voltage of  $0.76 \text{ V}$  and a maximum power density of  $7.7 \text{ mW cm}^{-2}$ . For comparison, the fuel cell is operated with carbon fiber cloth as electrocatalysts at both sides. The maximum power density is negligible with that of Ni-Co NWAs and Pd@CFC electrodes.

# Nature of Active Sites and Origin of Large Overpotential of the Oxygen Reduction Reaction on Pt(111) Surface

Junxiang Chen, Yuwen Liu, Shengli Chen  
*Department of Chemistry, Wuhan University, Wuhan, China*  
*slchen@whu.edu.cn*

The large overpotential of the oxygen reduction reaction (ORR) even on the best metal electrocatalyst, Pt, is one of the major barrier for the commercialization of fuel cells. Moreover, its origin has been a standing problem that challenges both the theoretical and experimental electrochemists. In this study, the problem is tackled by distinguishing the active sites from the surface spectator phases of oxygenated adsorbates through systematic density functional theory (DFT) calculations. By rationalizing the cyclic voltammetric (CV) features with the DFT-calculated adsorption isotherms for the oxygenation and reduction processes on Pt(111) surface, we conclude that there are mainly two types of oxygenated surface phases at potentials of ORR relevance (below ca. 1.07 V), namely, the  $(\sqrt{3}\times\sqrt{3})R30^\circ$ -patterned co-adsorption network of OH\*s and H<sub>2</sub>O\*s and the  $\sqrt{3}\times\sqrt{3}$ -structured O\*s. In a potential region below ca. 0.85 V, the electrode surface should be covered by a globally ordered OH\*s/H<sub>2</sub>O\*s network, while a pure phase of O\*s should form at potential above ca. 1.07 V. In between these potentials, the locally ordered OH\*s/H<sub>2</sub>O\*s networks and the clusters of O\*s coexist on the surface.

The correlation between the DFT-derived isotherms and that implied by the CV responses also suggests that the OH\*s and O\*s both prefer to form locally ordered phases during the oxygenation and reduction processes on Pt(111) surface, rather than distribute themselves randomly; the butterfly-shaped CV responses in the low potential region can be attributed to the competition between the energetically favoured Pt-OH\* bond formation and the energetically disfavoured decrease of the average distance of H<sub>2</sub>O\*s to the surface accompanying the dissociation of H<sub>2</sub>O\* to OH\* in the co-adsorption network; the highly unsymmetrical oxidative/reductive responses in the high potential region of CV is associated with the nucleation and growth type of formation of O\* clusters.

Various possible reaction channels for the ORR are investigated on Pt(111) surfaces covered by the two types of spectator phases. The results indicate that the surface phase of the  $\sqrt{3}\times\sqrt{3}$ -structured O\*s has much stronger blocking effect on the starting step in the ORR, namely, the adsorption reaction of O<sub>2</sub>, than the OH\*s/H<sub>2</sub>O\*s network phase. This suggests that the latter provides the main active sites for the ORR below ca. 1.07 V. The large onset overpotential and the potential-dependent Tafel slopes of the ORR are thus well explained in terms of the evolution of the strong spectator phase of O\*s with potential. A new type of proton/electron-transfer (PET) coupled O<sub>2</sub> adsorption step, in which the O<sub>2</sub> adsorption is accompanied by a PET to an OH\* in the OH\*s/H<sub>2</sub>O\*s network, rather than to the O<sub>2</sub> itself as generally believed, is identified to be the initial and also the activity-determining step in the ORR.

The present results show very distinct roles of various oxygenated adsorbates. The adsorbed oxygen atoms, O\*s, act mainly as surface spectators for the ORR. By forming hexagonal networks, OH\*s and H<sub>2</sub>O\*s also act as spectators to block the surface sites for the ORR. On the other hand, the formed networks provide reaction sites and environments for the ORR, with some OH\*s and H<sub>2</sub>O\*s participating into the reaction as intermediates and/or PET mediators. Therefore, the earlier proposition that OH\*s produced from water dissociation act solely as spectators, and that they are different in nature from OH\*s involved in the ORR, seems not correct. It is also implied that the binding strength of O\* impacts the ORR activity of Pt predominantly by modulating the numbers of the available O<sub>2</sub> adsorption sites, rather than the activation barriers or the natures of the rate-determining steps as proposed previously.

# Electron Transfer over Non-precious Metal Catalysts for Oxygen Reduction Reactions

Chang Hyuck Choi and Karl J. J. Mayrhofer

Department of Interface Chemistry and Surface Engineering, Max-Planck-Institut für Eisenforschung  
Max-Planck-Straße 1, 40237 Düsseldorf, Germany  
c.h.choi@mpie.de

In parallel with increasing global energy demands, polymer electrolyte membrane fuel cells (PEMFCs) have attracted great attentions as clean and efficient electrochemical energy conversion devices. As the nub of technology for high performing PEMFCs, catalysts are key components especially for overcoming sluggish kinetics of oxygen reduction reactions (ORRs). While Pt (or its alloys) has been widely used for the efficient ORRs, great recent efforts have been made to find non-precious metal catalysts for reducing high cost of the PEMFCs. Among the many candidates, FeNC catalysts, a class of catalysts consisting of Fe and N species doped on carbonaceous supports, demonstrate considerable ORR activity in an acidic environment [1, 2]. However, further developments have been still challenging because of less competent activity and stability.

For the maximizing catalytic performance, it is critical to understand the underlying electrochemical ORR mechanisms of the FeNC catalysts. Numerous experimental and theoretical studies have been substantially performed to figure out the ORR catalysis on the FeNC catalysts [3, 4]. Despite the ambitious efforts, however, the rational design of high-performing catalysts is still limited due to insufficient understanding on ORR catalysis of the FeNC, which is generally on the basis of an inner-sphere electron transfer (IS-ET) model that assumes  $O_2$  adsorption prior to the first electron transfer step [4].

Herein, we prepared the FeNC catalyst free from the inactive Fe species to address the importance of an outer-sphere electron transfer (OS-ET) mechanism during its ORRs. The prepared catalyst consisted dominantly with Fe- $N_4$  coordination sites with N-functionalities doped on the carbonaceous supports, thereby enabling to be considered as an ideal catalyst without interferences from the inactive Fe species. The FeNC showed irrational ORR behaviors in an acidic electrolyte such as no enhancement in  $H_2O_2$  selectivity in the presence of  $CN^-$  ions, low relationship between ORR activity and  $Fe^{2+/3+}$  redox potential, and activity loss without deformations of Fe-/N-species, which were not fully understood by the conventional belief that  $O_2$  adsorption precedes the ET step (IS-ET). To elucidate the electrocatalytic trends, we introduced a contribution of OS-ET mechanism in the first electron transfer step during the ORRs, and found that ORR activity of the FeNC was determined by the ionic strength in the electrolyte and by the electrode potential of the electrode. In accordance with the OS-ET mechanism, a linear relationship was established between work functions of the FeNC and their ORR activities after the degradation by  $H_2O_2$  treatment without any considerable deformations of  $O_2$  adsorption sites. The results therefore suggest an insight that contributions of the OS-ET and correlated tuning parameters as well as the traditional IS-ET should be also considered for the design of advanced FeNC catalysts in the future.

# Development of Sulfonated Poly(Arylene Ether Sulfone) Multi-Block Membranes for PEMFC Application

Byungchan Bae

Fuel Cell Laboratory, Korea Institute of Energy Research (KIER), 152, Gajeong, Yuseong, Daejeon, 305-343, Korea

E-mail: bcbae@kier.re.kr

Perfluorosulfonic acid (PFSA) polymers are the most promising state-of-the-art materials as proton exchange membranes (PEM) for fuel cells, however, there are some drawbacks such as high production cost and hydrothermal stability. Aromatic membranes based on hydrocarbon polymers have been studied as alternatives. Among them, multi-block copolymers seem to be promising to compete with PFSA resulting high proton conductivity even under low RH conditions.[1, 2]

In this report, novel sulfonated poly(arylene ether sulfone)s multi-block copolymer membranes containing highly sulfonated hydrophilic blocks were synthesized as shown in Figure 1.[3] Different local concentration of sulfonic acid in their hydrophilic blocks affected chemical and physical properties of the SPAES. To investigate the effects of chemical composition on their membrane properties, different hydrophilic oligomers sharing same hydrophobic blocks gave us exact comparison of effect of hydrophilic blocks. The higher concentration of sulfonic acid groups resulted in higher proton conductivity under certain relative humidity conditions than that of the state-of-the-art perfluorinated sulfonic acid membrane and showed that the well-developed phase separation of SPAES. Moreover, physical properties of these SPAES including water behavior, humidity dependence of proton conductivity were investigated along with morphology characterizations by transmission electron microscopy (TEM) for PEMFC application.

Figure 1. Concept for synthesis of the multi-block copolymer.

Two types of oligomers, F-terminated and OH-terminated telechelic oligomers, were synthesized by controlling the feed ratio of dihydroxyl- and difluoro-monomers. Their number of repeating unit (X and Y) was analyzed by GPC and  $^1\text{H}$  NMR. Copolymerization with F-terminated and OH-terminated telechelic oligomers via nucleophilic aromatic substitution, gave high-molecular-weight multi-block PESs. Each block length was controlled to have different values with X5Y10, X10Y10, X20Y10 and X20Y20.

The SPAES X10Y10 membrane showed highest proton conductivity than that of our previous random and block copolymers at wide range of humidity. The best balanced membrane was SPAES X10Y5 membrane with high proton conductivity and lower water uptake. Consequently, the SPAES X10Y5 membrane showed high cell performance under various conditions (510 mA/cm<sup>2</sup>, 290 mA/cm<sup>2</sup> @ 0.6V under 80% and 50 % RH conditions at 80°C, respectively). Systematic approaches for developing alternative block SPES membrane for low RH condition will be discussed.

# Challenges of NPGM Oxide Cathode for PEFCs

Ken-ichiro Ota<sup>a</sup>, Koichi Matsuzawa<sup>a</sup>, Shigenori Mitsushima<sup>a,b</sup>, Akimitsu Ishihara<sup>b</sup>

Yokohama National University,

<sup>a</sup>Green Hydrogen Research Center, <sup>b</sup>the Institute of Advanced Sciences

79-5 Tokiwadai, Hodogaya-ku, Yokohama, 240-8501 JAPAN

e-mail address: ken-ota@ynu.ac.jp

Polymer electrolyte fuel cells (PEFCs) are commercially available in Japan. Total number of installed Ene-Farm, the home cogeneration systems using PEFC, is over 12,000 and the thermal efficiency of over 90 % has been achieved. The commercialization of fuel cell vehicles has been started in Japan at the end of last year as the ultimate clean car due to their cleanness, high power density and low operating temperature. However, a cost reduction is needed and the cost of Pt is a key for the reduction. And the estimated amount of Pt reserve is too small to supply for the huge number of fuel cell systems. Pt is used for both anode and cathode catalysts. As a cathode catalyst, Pt has a large oxygen over potential compared to an anode. Pt has some instability in acid and oxygen containing atmosphere in nature. Pt is oxidized in oxygen containing atmosphere and PtO<sub>2</sub> is thermochemically stable at room temperature. Once Pt oxide is formed, the oxide could dissolve chemically. Pt oxide dissolves chemically and the solubility is around 1 ppm at room temperature in sulfuric acid. The dissolution followed the acid dissolution mechanisms. These things are chemical nature of Pt. In order to commercialize the fuel cell systems widely, the development of a non-precious metal cathode is strongly required.

We believe that high stability in cathodic condition is essentially required for the cathode catalyst. We started this study by searching stable materials in acid and in oxygen containing atmosphere by measuring the solubility in sulfuric acid. The solubilities of group 4 and 5 metal oxides are smaller than that of Pt in acidic and oxidative atmosphere. This means that these oxides are more stable than Pt at the cathodic condition of PEFC. However, these oxides are generally insulator. In order to get some electrical conductivity, these oxides should be modified by the formation of oxygen vacancy and/or the substitution of foreign atoms. We have reported that partially oxidized group 4 and 5 metal carbonitrides and metal complexes which contain nitrogen were stable in an acid solution and had a definite catalytic activity for the oxygen reduction reaction (ORR) (1-4). In this paper we will report the reasons why we need a non platinum group metal (NPGM) oxide cathode and our recent results of the oxide cathode for PEFCs.

Powders of metal (Metal: Ta, Zr, Nb, Ti) compounds (carbonitride or metal complexes that contain nitrogen) were heat-treated at 800-1200°C. After heat treatment, the compounds changed to oxides that contained small amount of carbon and nitrogen. Heat treated powder was mixed with alcohol, carbon and Nafion. The mixture was dipped on a glassy carbon rod (5 mm diameter) and the working electrode was made. All electrochemical measurements were examined in 0.1 M H<sub>2</sub>SO<sub>4</sub> at 30°C under atmospheric pressure using a conventional 3-electrode cell. The RHE was used for the reference in the same solution. Slow scan voltammetry (scan rate: 5 mVs<sup>-1</sup>) was performed under O<sub>2</sub> and N<sub>2</sub> atmosphere to obtain the current for the oxygen reduction reaction (ORR).

An appropriate oxidation is essential to have a definite catalytic activity for the ORR. In order to improve the current density especially at high potentials we have tried to use metal complexes that have nitrogen as starting materials. More than 1000 times improvements in catalytic activity have been obtained using these materials. By the single cell test we have obtained more than 300 mA/g at 0.85 V vs. RHE for ORR at room temperature. We also have obtained more than 1 A/cm<sup>2</sup> using a 5 x 5 cm fuel cell at 80°C. These materials have great potential for PEFC cathode,.

There has been considerable interest in alkaline anion exchange membranes (AAEMs) fuel cells as high efficiency, low emission, energy converters.<sup>1</sup> In contrast to the platinum used in proton exchange membrane fuel cells, AAEMFC use cheaper, non-noble metal catalysts, thereby potentially giving them a considerable advantage.<sup>2</sup> However, development of AAEMs has been hindered by the instability of commonly-used cationic groups (e.g., ammonium, phosphonium) under conditions of high pH and elevated temperature. While progress has recently been made in this area, virtually all AAEMs studies have focused on the issue of degradation rather than attempts to obtain a phenomenological understanding of how polymer structure and ionic content relate to observed membrane properties (e.g., anionic conductivity).

At Simon Fraser University, we have been developing benzimidazolium-based anion exchange membranes (AEMs) for a variety of applications, including AAEMFCs.<sup>3</sup> Very recently, we have developed a synthetic method that allows us to control the ionic content of these polymers.<sup>3c</sup> Using this technique, we have now been able to compare the properties not only between polymers with different backbone structures (examples shown below) but also within each series wherein ionic content is varied in a controlled fashion. This presentation will detail the results of our exploratory work on structure-property relationships for these methylated poly(benzimidazoles).

# The Performance and Stability of the Oxygen Reduction Reaction on Pt-based Nanorods: An Experimental and Computational Study

Kuan-Wen Wang<sup>a</sup>, Jeng-Han Wang<sup>b</sup>, Yu-Ting Liang<sup>a</sup>

<sup>a</sup> Institute of Materials Science and Engineering, National Central University, Taoyuan 320, Taiwan

<sup>b</sup> Department of Chemistry, National Taiwan Normal University, Taipei 116, Taiwan

E-mail: kuanwen.wang@gmail.com

The development of Pt-based catalysts towards the oxygen reduction reaction (ORR) for polymer electrolyte membrane fuel cells (PEMFCs), through control of the morphology, alloying components, structures, and supports has attracted much attention. When compared with Pt nanoparticles (NPs), graphene or carbon-supported Pt nanomaterials with different aspect ratios, alloying components or morphologies especially nanorods (NRs) have shown enhanced ORR performance owing to the electronic modification effect.<sup>1-5</sup> In this study, we have investigated the ORR activity and stability of Pt<sub>3</sub>M (M = Au, Ag, and Pd) NRs, which have potentially good activity and stability, both experimentally and computationally. Pt<sub>3</sub>M NRs with an aspect ratio of 4.0 have been prepared to study their ORR activity and stability by electrochemical measurement and Density functional theory (DFT) calculations. The ORR activity of Pt<sub>3</sub>M NRs is related to the degree of modification of the oxophilicity ( $\Delta E_{ads}$ ), which is the difference between  $E_{ads}(\text{O}^*$  or  $\text{OH}^*)$  for Pt and its alloys. DFT results suggest that since  $\Delta E_{ads}$  of PtPd NRs is -0.11 eV, the modification effect of alloying with Pd is insignificant. On the other hand, Au can noticeably modify the Pt surface so that the  $\Delta E_{ads}$  is 0.47 eV. However, due to the oxygen containing species (OCS\*) induced Pt surface segregation, the structure of PtAu becomes unstable during accelerated durability test (ADT). As a result, although the  $\Delta E_{ads}$  of PtAg is not as high as that of PtAu, the structure is relatively stable with or without OCS\*, thus promoting the ORR stability with a decay of 9 % during ADT.<sup>6</sup>

# The Steady State coverage of oxygenated species on Platinum and its influence on the Oxygen Reduction and Hydrogen Oxidation Reaction in acid electrolyte

Yu-Jia Deng, Gustav K.H. Wiberg, Matthias Arenz

Nano-Science Center, Department of Chemistry, University of Copenhagen, Universitetsparken 5, DK-2100 Copenhagen Ø, Denmark

[dengyujia@chem.ku.dk](mailto:dengyujia@chem.ku.dk)

In this work, we employ a recently developed stripping technique to investigate the equilibrium coverage of oxygenated species such as  $\text{OH}_{\text{ad}}$  and  $\text{O}_{\text{ad}}$  and how they influence the oxygen reduction reaction (ORR) and the hydrogen oxidation reaction (HOR) [1]. The main aim is to distinguish between dynamic and steady state conditions and find out whether the different respective oxygenated species  $\text{OH}_{\text{ad}}$ ,  $\text{O}_{\text{ad}}$  and Pt-oxide dominate distinctive potential regions. As is shown in Fig. 1, at steady state in Ar saturated 0.1 M  $\text{HClO}_4$  electrolyte only insignificant amounts of oxygenated species are observed  $< 0.60 \text{ V}_{\text{RHE}}$  and no influence on the HOR or ORR is seen. The first adsorbed species is  $\text{OH}_{\text{ad}}$  and at  $0.95 \text{ V}_{\text{RHE}}$  the adlayer is completed. With increasing potential  $\text{OH}_{\text{ad}}$  can be oxidized further to  $\text{O}_{\text{ad}}$  and at  $1.1 \text{ V}_{\text{RHE}}$ , only  $\text{O}_{\text{ad}}$  is on the surface. An oxide is formed at even more positive potentials. We also conduct the experiment by changing Ar to  $\text{O}_2$  or  $\text{H}_2$  saturated solution, we find that the inhibition of ORR correlates with the completion of the  $\text{OH}_{\text{ad}}$ -layer and only at more negative potentials than  $0.95 \text{ V}_{\text{RHE}}$ , the ORR can proceed. HOR is however active up to about  $1.1 \text{ V}_{\text{RHE}}$ , as it can alter the  $\text{OH}_{\text{ad}}$  coverage [2].

In the next step, we compare the different behaviour towards the ORR on polycrystalline Pt in three different acids with varying anion adsorption strength, i.e.  $\text{HClO}_4$ ,  $\text{H}_2\text{SO}_4$  and  $\text{H}_3\text{PO}_4$ . We will present unexpected results, leading to a new model for explaining the influence of anions for the inhibition of the ORR in  $\text{H}_3\text{PO}_4$  as compared to  $\text{H}_2\text{SO}_4$  or  $\text{HClO}_4$ .

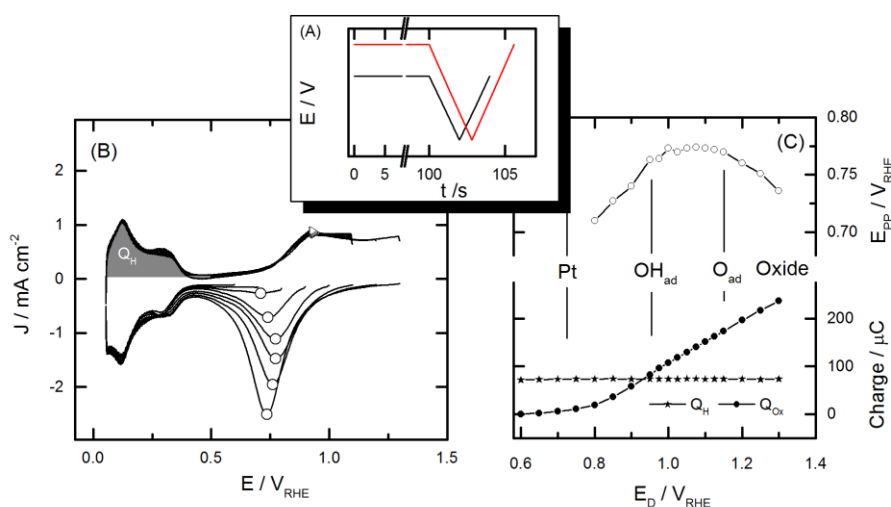

Fig. 1. (A) Examples of applied voltage profiles: the potential hold at ( $E_D$ ) is followed by a negative and positive sweep at a sweep rate of  $0.5 \text{ V s}^{-1}$ . (B) Polarization curves of PC Pt in argon saturated in 0.1 M  $\text{HClO}_4$  for different hold potentials. Key features have been highlighted: charge integration of the oxide peak ( $Q_{ox}$ ) and  $H_{upd}$  features ( $Q_H$ ) as well as the oxide reduction peak position ( $E_{pp}$ ). (C)  $E_{pp}$ ,  $Q_{ox}$  and  $Q_H$  versus hold potentials [2].

## **Evolution of “ENE-FARM” and the Activities for the Market Expansion in Panasonic**

Eiichi Yasumoto, Masataka Ozeki  
*Corporate Engineering Division, Appliances Company*  
*Panasonic Corporation*  
*3-1-1 Yagumo-naka-machi, Moriguchi City, Osaka 570-8501, Japan*  
*yasumoto.eiichi@jp.panasonic.com*

ENE-FARM is a residential fuel cell cogeneration system which simultaneously produces electricity and hot water as a distributed power source. The heat produced during power generation can be used for water heating, so it contributes to primary energy saving by its high efficiency and also boosts energy security.

The cumulative sales of ENE-FARM, which became the world's first residential fuel cell when it was released in Japan in May 2009, reached 100,000 units in September 2014. As mentioned above, the market is expanding with strong support from the government. But in order to be a self-sustained business, big cost-reduction is required from fuel cell manufacturers and we need to continue our challenge to create and enlarge the fuel cell market.

To achieve this goal, Panasonic has updated the model every 2 years. We have recently released a new model (4<sup>th</sup> generation) fuel cell in April 2015. We achieved in driving down the end user price to 1.6 million JPY.

Also, compared to the previous model, the number of components has been reduced by 15% and also the weight of the total system is reduced by 15% (from 90kg to 77kg).

And we have improved stack performance it has been optimized the MEA, so there is a 20% reduction in the rare-metal Platinum used for the stack. In addition to the cost reduction, we increased product durability from 60,000 hours to 70,000 hours and adopted the continuous power generation mode into the unit.

Additionally, Panasonic started a new challenge from April 2014. We launched a new model with the German heating appliance manufacturer, Viessmann, for the German market. Based on the bigger heat demand and cost difference between electricity and gas price, we believe that it has a big market potential in European countries.

Panasonic believes that ENE-FARM has a big role with regard to energy management with high efficiency, supporting renewable energy, and the focus on local energy management using decentralized power systems. Fuel cell is the core technology to establish the hydrogen society of the future. Panasonic will continue to contribute to make a better life, a sustainable and safe society and the solution to environment issues in co-operation with global partners.

In this presentation, introduction of the latest model ENE-FARM in Panasonic and its elemental technology will be reported.

# Preparation and Properties of PTFE Reinforced Novel Anion Exchange Membranes Based on Silane Crosslinked Imidazolium Containing Poly(2,6-dimethyl-1,4-phenylene oxide)

Jingshuai Yang, Chao Liu, Liping Gao, Yixin Xu, Niya Ye, Ronghuan He\*

Recently, alkaline anion exchange membrane fuel cells (AEMFCs) have attracted extensive attention due to several advantages, such as non-use of noble metals as catalyst, much more facility of electrochemical reactions<sup>[1]</sup>. The anion exchange membrane (AEM) is the core of an AEMFC, which should meet with high conductivity, low swelling, enough mechanical strength and good stability under strong basic environment and elevated temperatures<sup>[1,2]</sup>.

Through bromination of alkyl side chains, bromomethylated poly(2,6-dimethyl-1,4-phenylene oxide) (BPPO) polymers were synthesized with bromination degrees from 20% to 71%. In order to achieve high conductivity, the polymer with high bromination degree of 71% was used to fabricate cross-linked membranes. The imidazolium functionalization of the membranes were performed by reacting BPPO with methylimidazole and imidazolium-functionalized silane simultaneously. The crosslinked network was then formed by hydrolysis in an acid medium. The chemical structure of the crosslinked membranes is shown in Fig.1. Moreover, the polytetrafluoroethylene (PTFE) was used as a matrix polymer to reinforce the mechanical stability<sup>[3]</sup> to obtain uniform composite membranes. Results illustrated that the conductivity of membranes increased as the increase of methylimidazolium groups in the membranes. For example, the conductivity of the membrane with an molar ratio of 7:3 for methylimidazolium and imidazolium-modified silane was higher than 30 mS cm<sup>-1</sup> in water at temperatures of 80 °C, which also possessed enough mechanical strength. The results indicated that the PTFE reinforced imidazolium-modified silane cross-linked membranes can be used as membrane electrolytes for AEMFCs.

Platinum is widely used as electrode catalyst in Solid Polymer Electrolyte Fuel Cells (SPE-FCs) but it is an expensive material and not abundantly available. For these reasons lots of works have concentrated to develop and search for alternative electrode materials. As platinum group metals (PGM) must be, step by step, replaced by less costly and available transition metals (TM) for a widespread application of these sustainable energy sources, efforts are being made either to decrease the noble scarce metals or to “dilute” their content with TM co-catalysts addition [1]. For this concern, palladium, that is more abundant on earth than Pt and known to have excellent ability toward the oxygen reduction reaction (ORR), is herein used as cathode material in a H<sub>2</sub>/O<sub>2</sub> SPE-FC. Understanding the material structure provides relevant information on its catalytic properties. On this objective, carbon supported PdM (M = Cu, Ni and Ag) nanomaterials were synthesized from the microwave-assisted heating method [2]. The crystal structure and crystallite size, the chemical composition and morphology of the homemade catalysts were performed with various physicochemical techniques prior to their electrochemical characterization with O<sub>2</sub>-saturated diary electrolytes.

The presentation will look at the electrical performances a 5 cm<sup>2</sup> single SPE-FC at 80 °C using low catalysts loadings (0.4 mg cm<sup>-2</sup>) in the membrane electrode assembling. As finding, the microwave heating method has been successfully used for preparing Pd-based cathode materials with small particle size, which deliver 480 mW cm<sup>-2</sup> at 1.4 A cm<sup>-2</sup>.

Figure 1. Cell voltage and power density obtained in a 5 cm<sup>2</sup> single H<sub>2</sub>/O<sub>2</sub> SPE-FC with Nafion<sup>®</sup> 115 membrane at 80 °C: (-) Pt (0.4 mg cm<sup>-2</sup>) / H<sub>2</sub> (3 atm) // O<sub>2</sub> (3 atm) / PdM (0.4 mg cm<sup>-2</sup>) (+).

# A Novel Approach to Develop MIEC material: CeO<sub>2</sub>-ZrO<sub>2</sub> composite

Aditya Maheshwari and Hans-Dieter Wiemhöfer

*Institute of Inorganic and Analytical Chemistry, University of Muenster, Germany.*

*Corrensstrasse 28/30, 48149 Muenster*

*e-mail address: [a.maheshwari@uni-muenster.de](mailto:a.maheshwari@uni-muenster.de) (A. Maheshwari)*

*[hdw@uni-muenster.de](mailto:hdw@uni-muenster.de) (H.-D. Wiemhöfer)*

Mixed ionic electronic conductors (MIECs) such as doped ceria as well as zirconia have been studied for their applications in a wide range as anode additives, electro catalysis, gas separators etc. [1-5]. Although with the acceptor doping, ceria shows a good MIEC behavior but only at very low oxygen partial pressures, where Ce<sup>4</sup> reduces to Ce<sup>3+</sup> generating electrons. In this case electronic conductivity becomes nearly equal to the ionic conductivity in the range of 10<sup>-10</sup>-10<sup>-15</sup> bar *p*(O<sub>2</sub>). However, at normal *p*(O<sub>2</sub>), acceptor doped ceria has a negligible electronic conductivity. On the contrary, in donor doped ceria, ionic conductivity is negligible at normal *p*(O<sub>2</sub>). Mixing the two effects by doping with donor+acceptor dopants does not enhance the MIEC behavior but decreases the effective conductivity due to the cancellation of the opposite effects from donor and acceptor dopants [6].

In the present work, an approach to produce MIEC CeO<sub>2</sub>-ZrO<sub>2</sub> composite materials is developed. In past, these ceria-zirconia composites drew a great deal of attention as additive layers between the electrolyte and electrode. However, the most emphasis has been given to the ionic conductivity [7-9] and not a substantial research has been done on developing these CeO<sub>2</sub>-ZrO<sub>2</sub> composites as MIEC materials. The present work addresses this approach and for this purpose, Ta<sup>5+</sup> doped ceria (TDC) and YSZ, well-known electronic and ionic conductors, respectively, have been taken as base oxide materials. The samples are prepared *via* classical mixed-oxide route using Acetone as medium. The powders were dried/calcined at 400 °C and subsequently pressed in the form of circular pellets. Pressed pellets were sintered and then used for impedance and Hebb-Wagner measurements.

The samples with TDC to YSZ weight ratio of 1:1 and 2:1 were investigated, as a first step. The samples showed conductivities lower than that of each of the two separate constituents, TDC and YSZ. This can be attributed to a highly resistive interface between the ceria and zirconia particles. In order to decrease this interface resistivity, in a first attempt the electronic resistance was reduced by doping 1 mol% Co. A further reduction in the grain boundary resistivity was achieved by adding 20 wt% Na<sub>2</sub>CO<sub>3</sub>. We attribute this to an additional improvement of the ionic part of the grain boundary conductivity. The results overall showed a nearly 10 times higher conductivity with Co<sup>2+</sup> and a nearly 10 000 times higher conductivity after Na<sub>2</sub>CO<sub>3</sub> addition in the final TDC-YSZ composite. Furthermore, to combine the separate effects of Co and Na<sub>2</sub>CO<sub>3</sub>, the composites with 1 mol% Co + Na<sub>2</sub>CO<sub>3</sub> addition were prepared and investigated for their total and electronic conductivities, separately. The amounts of both the additives were optimized afterwards and final doped TDC-YSZ sample showed a good ionic as well as electronic conductivities. Hence, the use of both CoO and Na<sub>2</sub>CO<sub>3</sub> as additives leads to a greatly optimized mixed conducting ceramic composite with a remarkably increased net conductivity for ions and electrons in the intermediate temperature range. A detailed overview will be provided in the presentation during the meeting.

[junfu@kth.se](mailto:junfu@kth.se)

The effects of NiO on the sintering behaviors, morphologies and conductivities of  $\text{BaZr}_x\text{Ce}_{0.8-x}\text{Y}_{0.2}\text{O}_{3-\delta}$  ( $x = 0.5, 0.6, 0.7, 0.8$ ) proton conductors were systematically investigated. 1 wt.% NiO powder was added by different methods during the sample preparations: (i) added during ball-milling before powder mixture calcination, (ii) no NiO addition in the whole preparation procedure and (iii) added after powder mixture calcination. The conductivities of these dense  $\text{BaZr}_{0.5}\text{Ce}_{0.3}\text{Y}_{0.2}\text{O}_{3-\delta}$  (BZCY532),  $\text{BaZr}_{0.6}\text{Ce}_{0.2}\text{Y}_{0.2}\text{O}_{3-\delta}$  (BZCY622),  $\text{BaZr}_{0.7}\text{Ce}_{0.1}\text{Y}_{0.2}\text{O}_{3-\delta}$  (BZCY712) and  $\text{BaZr}_{0.8}\text{Y}_{0.2}\text{O}_{3-\delta}$  (BZCY802) ceramics were investigated in dry air, wet  $\text{N}_2$  and wet  $\text{H}_2$  atmospheres, respectively. Furthermore, their electronic conduction were also identified in a broad oxygen partial pressure range from 1 atm to  $10^{-24}$  atm. According to current achieved results, it can be concluded that it is preferable to add the NiO during powder preparation, which can lower the sintering temperature and also increase the conductivity of BZCY532-based electrolytes.

# Effects of H<sub>3</sub>PO<sub>4</sub> leaching on the performance and degradation of high temperature-proton exchange membrane fuel cells

## Abstract

The impact of H<sub>3</sub>PO<sub>4</sub> electrolyte leaching on the performance and degradation of polybenzimidazole fuel cells were investigated in the temperature range of 120~190 °C without gas humidified. From test results of cell performance indicated that the best cell's assembly pressure and operating temperature are at 60 kgf-cm and 180 °C, while the cell has a minimum internal impedance (~4 mΩ). The cell was operated over 600 hrs continuously at high current loading (500 mA/cm<sup>2</sup>), the cell's average voltage decay rate was 1.58 mV h<sup>-1</sup>. The H<sub>3</sub>PO<sub>4</sub> content in water discharged from the cell outlet was measured by using acid-base titration method. The amount of H<sub>3</sub>PO<sub>4</sub> on the cathode side is 3.5 times on the anode side, and the total amount of H<sub>3</sub>PO<sub>4</sub> leaching was about 30 mg. Further from the electrochemical impedance spectroscopy (EIS) analysis, we found that the cell's internal resistance and charge transfer resistance are increased significantly with the H<sub>3</sub>PO<sub>4</sub> leaching. However, there is no mass transfer limiting behavior observed on Nyquist plots at low frequencies region. These results are quite in consistent to the cell's IV polarization curve.

In order to reduce the cost of solid oxide fuel cells (SOFCs), less expensive and more conductive metallic interconnects have been recently used to replace ceramic interconnects for intermediate temperature applications<sup>1-3</sup>. Metallic interconnects commonly use chromium-containing alloy that form chromia scales at high temperatures. However, chromium oxide easily reacts with perovskite cathode causing ion diffusion and degradation in electrical conduction.

To suppress the growth of chromium oxide, a protective oxide layer with adequate electronic conductivity may be thermally sprayed on the surface of metallic interconnect. Conducting oxides with either perovskite or spinel structure were deposited on metallic interconnect using thermal spray technique in this study. Due to the high deposition temperature during thermal spray coating, the structural and conduction properties of the protective oxides are strongly affected by the thermal spray process. For example, the dramatic change in temperature during thermal spray may change the crystal structure and then conductivity of protective oxide.

Thus, the objective of this work is to investigate the effect of thermal reduction/oxidation on the structural properties of protective oxides. The crystal structure, morphology and electrical conduction of oxide films and metallic substrate were examined by using XRD, FESEM and resistance measurement.

Solid oxide fuel cells(SOFCs) have been known as the desired conversion devices for electricity generation by an electrochemical reaction of a fuel with an oxidant. In SOFC, oxygen ion conductors are commonly used as the electrolytes. Among several oxygen ion conductors such as CeO<sub>2</sub>, stabilized Bi<sub>2</sub>O<sub>3</sub> and ZrO<sub>2</sub>, Bi<sub>2</sub>O<sub>3</sub>-based systems show the highest oxygen ion conductivity. The resistance of Bi<sub>2</sub>O<sub>3</sub> against reduction may be enhanced by the addition of proper dopants. However, the OCV of SOFC using Bi<sub>2</sub>O<sub>3</sub>-based electrolyte is still too low to be practical. On the contrary, Bi<sub>2</sub>O<sub>3</sub>-based system may become a good ionic component for a composite cathode.

In this study, Y<sub>2</sub>O<sub>3</sub>-stabilized Bi<sub>2</sub>O<sub>3</sub> (YSB) is mixed with Sr-doped LaMnO<sub>3</sub> (LSM) to form a composite cathode. The volume fraction and size effect of LSM on the polarization resistance were investigated at various temperatures ranging from 500°C to 650°C using a symmetric cell consisting of LSM-YSB composite electrodes on both side of the electrolyte.

The reduced polarization measured from composite cathode was observed from the samples that mixed YSB with very fine LSM powder. Compared to submicron-sized LSM, the polarization resistance measured from nano-sized LSM-YSB composite electrodes is 50% lower at 650°C. It is believed that the composite cathode with desired nanostructure is able to extend triple phase boundary and provide numerous reaction sites for electrochemical reaction to occur. In additions, the composite electrodes using LSM-YSB combination also shows lower polarizations than LSM-SDC and LSM-YSZ combinations

# Conductive oxide supported Co<sub>3</sub>O<sub>4</sub> nanocomposite as robust catalysts for oxygen reduction and evolution reaction

Oxygen reduction reaction (ORR) and oxygen evolution reaction (OER) are the heart of several renewable energy technologies such as water electrolysis, metal-air batteries, and fuel cells. Recently, carbon supported Ru based catalysts have been reported as high performance catalyst for oxygen evolution reaction. However, Ru based catalysts suffers from high cost and severe degradation in electrocatalytic activity after long term operation.

In this study, we synthesized transition metal doped TiO<sub>2</sub> via solvothermal synthesis as electrocatalyst support in alkaline media. The metal-doped TiO<sub>2</sub> (M-TiO<sub>2</sub>) is expected to exhibit high stability at operational conditions and can be used as a bifunctional support for both ORR and OER reaction. Then, cobalt oxide will be deposited on transition metal doped TiO<sub>2</sub> as co-catalyst via hydrothermal processes. The cobalt oxide M-TiO<sub>2</sub> nanocomposite shows high activity and stability for both OER and ORR reaction compared to bare cobalt oxide and M-TiO<sub>2</sub> support. The catalytic enhancement might be resulted from the synergic effect between cobalt oxide and M-TiO<sub>2</sub> support. The developed nanocomposite would be a promising system to replace Pt and can be adapted as bifunctional catalysts for both oxygen reactions.

# Preparation of Highly Conductive TiO<sub>2</sub> Supported Pt Catalyst and Its Electrochemical Performance

The long-term performance of polymer electrolyte membrane fuel cells (PEMFCs) that depend on the stability of support can be improved by using highly stable metal oxides to replace carbon which occurs electrochemically corrode during cell operation. In this work, highly-conductive TiO<sub>2</sub> supported Pt catalysts were synthesized and electrochemical performance was investigated for use in fuel cell application. First, TiO<sub>2</sub> nanoparticles were synthesized using a solvothermal method. SiO<sub>2</sub> coating was then applied to the TiO<sub>2</sub> nanoparticle surface by using the Hexamethyldisilazane method (HMDS) in order to inhibit the particle growth during heat treatment under H<sub>2</sub> environment. The phase of TiO<sub>2</sub> nanoparticles changed from anatase phase to rutile phase and eventually transformed to Magnéli phase when the temperature rises to 1000°C. It was found that the electrical conductivity of TiO<sub>2</sub> increases with increasing reduction temperature but at the cost of decrease in the surface area. The electrochemical performance shows that Pt catalyst, loaded on the TiO<sub>2</sub> support which is treated by the HMDS method and H<sub>2</sub> reduction, exhibits the good reactivity for methanol oxidation reaction (MOR) and oxygen reduction reaction (ORR). Such performance is attributed to a higher surface area and improved electrical conductivity. Durability test show that TiO<sub>2</sub> supported Pt catalyst has better stability and anti-corrosive abilities when compared to the commercial catalyst (JM20).

# Structural Stability of Mixed Conducting $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$ ( $x=0\sim 0.4$ ) Perovskite in Different Atmospheres

Chung-Ta Ni, Shu-Yi Tsai, Kuan-Zong Fung, Yu-Cheng Su, Han-Lung Liu  
*Department of Materials Science and Engineering, National Cheng Kung University*  
*No.1 University Road, Tainan City, Taiwan 70101*  
*chungtani@gmail.com*

Perovskite type  $\text{LaFeO}_3$  is a mixed ionic/electronic conductor exhibits good stability at various oxygen partial pressure, however  $\text{LaFeO}_3$  showed low conductivity which also limited its applications. The addition of aliovalent dopants is known to be an effective way to enhance the conductivity of many perovskite oxides. The objective of this work is to enhance the conductivity of  $\text{LaFeO}_3$  by using the method of double doping in perovskite's cation sublattices. For instance, Ca ions was added into A-site cation sublattice for substitution of La ions. On the other hand, Co ions were added into B-site cation sublattices for substitution of Fe ions. The samples were prepared using solid state reaction method based on the formula of  $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$  ( $x=0\sim 0.4$ ). After sintering at  $1300^\circ\text{C}$ , the powder compacts with various compositions were densified. All the  $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$  samples showed typical p-type semiconducting behavior with increasing conductivities at higher temperatures. The addition of Co tends to enhance the conductivity of  $\text{La}_{0.8}\text{Ca}_{0.2}\text{FeO}_3$ . When 40% of B-site cation sublattice was replaced by Co ions, the conductivity of  $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$  was enhanced from 90 S/cm to 255 S/cm. However, the stability of  $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$  tends to decrease with increasing amount of Co addition. For instance, 40% Co-doped  $\text{La}_{0.8}\text{Ca}_{0.2}\text{Fe}_{1-x}\text{Co}_x\text{O}_3$  was found to decompose into  $\text{La}_2\text{O}_3$  and metallic Co, Fe when the sample was heat-treated with 10% $\text{H}_2$  at  $800^\circ\text{C}$ . The enhancement in conductivity and instability in reducing atmosphere will be rationalized in light of defect chemistry and bond strength between the transition metal and oxygen ions.

The effect of Nafion on oxygen reduction reaction (ORR) activity of proton exchange membrane fuel cell catalysts has recently been studied by using rotating disk electrode (RDE) methods on single crystalline, polycrystalline Pt surfaces and nanostructured thin film (3M NSTF) in 0.1 M HClO<sub>4</sub> [1-5]. In these studies, thin ionomer films (nm to 10's of nm) were applied to the electrode surfaces by capping with ionomer. A positive shift on the onset potential for OH and other oxide species formation and a suppression of the ORR activity is typically observed after capping. Subbaraman et al. [1] attributed the features observed on cyclic voltammograms under inert atmosphere to sulfonate anion adsorption on Pt surfaces using a CO displacement method. In addition, based on the parallel activity trend on Pt (111), (110) and (100) surfaces with that obtained in sulfuric acid solution, they concluded that sulfonate anion adsorption was the main cause for lowered ORR activity. In contrast to these detailed kinetics studies on well-defined Pt surfaces, little work has been reported on Pt/C catalysts [6]. The lack of studies can be considered as a consequence of following aspects: (i) ionomer inclusion in a catalyst ink tends to increase ink dispersion in sonication (ii) elimination of ionomer from the ink can result in poor catalyst film quality (iii) ionomer is often used to glue catalysts on substrate surfaces such as glassy carbon [7]. However, we have recently discovered that ionomer is not necessary to obtain well-dispersed stable thin catalyst films [8]. Moreover, the use of extremely thin and uniform films is indispensable to the kinetics study of ORR catalysts without hindrance from O<sub>2</sub> diffusion limitations within the catalyst layer.

In this work, we have investigated the effect of Nafion ionomer on the ORR activity as well as CVs under inert atmosphere for several commercial Pt/C and Pt Alloy/C catalysts by employing thin-uniform catalyst films obtained by advanced film fabrication techniques [8]. Nafion capped catalyst films were obtained by applying a diluted Nafion solution on Nafion-free films followed by drying in air at 23°C. Figure 1 depicts ionomer to carbon (I/C) ratio dependence of the specific activity of various catalysts at 0.9 V vs. RHE in 0.1 M HClO<sub>4</sub>.

**Figure 1.** I/C dependence of SA for Pt/C and PtCo/C catalysts (0.1 M HClO<sub>4</sub>, 20 mVs<sup>-1</sup>, -0.01 to 1.0 V, 100kPa O<sub>2</sub>, 23°C).

# Simulated Design of High-altitude Long-endurance Unmanned Aerial Vehicles using Regenerative Fuel Cell Systems

Minjin Kim, Young-Jun Sohn, and Tae-Hyun Yang  
Korea Institute of Energy Research, Fuel Cell Research Center  
152 Gajeong-ro, Yuseong-gu, Daejeon, 305-343, Republic of Korea  
minjin@kier.re.kr

Recently, unmanned aerial vehicles (UAVs) have been tried to apply to commercial missions such as meteorological observation, communication, and internet network as well as traditional military missions. Research works about high-altitude long-endurance (HALE) UAVs are especially focused on those applications. A regenerative fuel cell (RFC) system is one of solutions to achieve HALE of UAVs. RFC consist of a fuel cell, gas tanks, and water electrolysis. The RFC-solar cell hybrid system can operate without additional fuel supplement for a long time. However there are actually some limitations for the HALE UAVs based on RFC systems. Performance factors in terms of the weight and efficiency of RFC components should be more improved. In this study, feasibilities of HALE for RFC based UAVs have been checked on the current technology basis. In detail, flight stability of the RFC hybrid UAV according to the architecture and component's specifications has been known. Furthermore some solutions for substantial and stable HALE of the target UAV are considered.

\*patcorradini@gmail.com

The demand for power sources for portable and stationary applications is increasing significantly. Fuel cell (FC) systems with higher energy density are seen as a potential candidate to fill the growing gap between energy demand and supply for mobile applications. [1] The direct ethanol fuel cell (DEFC) has attracted much attention from researchers and manufacturers, and several efforts were implemented to improve its performance of catalysts electro-activity for ethanol oxidation. Several studies based on bimetallic catalysts reported that the best catalyst is PtSn, since it has higher current densities and ethanol oxidation reaction (EOR) has lower onset potential than on platinum. The modified PtSn/C electrodes with rare earths gradually have been reported to improve the EOR kinetics. [2] This paper evaluated the effect of Eu addition on the catalytic activity and stability of PtSn/C catalysts. The PtSnEu/C catalysts were obtained by a modification of polyol procedure propose by Sun *et al.*[3] All materials are 20 wt% of metal (Pt+Sn+Eu) on carbon, and different metal atomic proportions were evaluated. All catalysts were characterized by EDX, XDR, TEM and XPS. The XRD patterns of commercial Pt/C and PtSn/C; and different PtSnEu/C catalysts are shown in Fig.1a. For all catalysts, the first peak is the diffraction of the (002) plane of the hexagonal structure of carbon. The diffraction peaks at around 39, 46, 68 and 81° are corresponding to Pt (111), (200), (220) and (311) planes, respectively, which indicates that the Pt exists in the face centered cubic (fcc) phase. The diffraction peak of the (220) plane on PtSn/C and different PtSnEu/C catalysts slightly shifts to lower  $2\theta$  values with respect to the corresponding peak on Pt/C, indicated the incorporation of Sn atom into the lattice of Pt. Although the diffraction peaks associated with metallic Sn and Eu or their oxides do not appear in the patterns, their presence cannot be discarded since Sn and Eu may appear in the form of PtSn alloy or their oxides with amorphous structure. DEFC polarization and power density curves at 90 °C using Pt/C, PtSn/C and PtSnEu/C as anode catalysts are shown in Fig. 1b. The DEFC with PtSnEu/C as anode catalysts showed the best performance for all current densities. The PtSnEu (70:15:15) showed the power density around 13 mW cm<sup>-2</sup> at 35 mA cm<sup>-2</sup>. The experimental results revealed that the addition of Eu to PtSn/C catalyst can significantly enhance the catalytic activity for ethanol oxidation. Probably, the europium oxides can promote the formation of OH species, which facilitate the removal of adsorbed intermediates, and to improve the PtSn/C catalytic. [4]

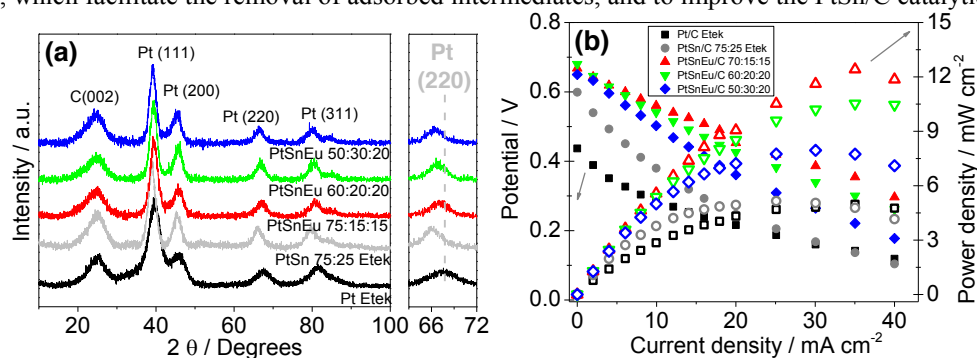

Figure 1. (a) X-ray diffraction patterns for PtSnEu/C electrocatalysts. (b) Polarization and power density curves obtained in a single DEFC with Pt/C, PtSn/C and PtSnEu/C as anode electrocatalysts for ethanol oxidation at 90 °C and 3 atm O<sub>2</sub> pressure, using a 1 mol L<sup>-1</sup> ethanol solution. Cathode: 30 wt% Pt/C. Metal loading for anode and cathode: 1 mg<sub>Pt</sub> cm<sup>-2</sup>.

# Development of a cathode material for durable PEFC through the encapsulation of Pt into carbon mesopores

Akari Hayashi<sup>a,b,c,d</sup>, Yasuto Minamida,<sup>b</sup> Zhiyun Noda,<sup>a,b</sup> and Kazunari Sasaki<sup>a,b,c,d</sup>  
Kyushu University <sup>a</sup>International Research Center for Hydrogen Energy, <sup>b</sup>Faculty of Engineering,

hayashi.akari.500@m.kyushu-u.ac.jp

Reduction of Pt active sites over time is a serious issue for practical use of PEFC. A few nanometer Pt particles on carbon supports have tendency to agglomerate, or dissolve and re-precipitate to under the potential change, resulting in formation of larger particles. In this study, suppressing such Pt particle growth and then increasing durability of electrocatalysts are targeted by reducing the mobility of Pt particles on the carbon support. Principally, Pt particles are introduced into nanochannels of mesoporous carbon (MC), whose diameter is ca. 10 nm. The idea comes from increased stability on the curved surface comparing to flat surface. This idea is also supported by theoretical study.<sup>1</sup>

Electrocatalysts were synthesized from platinum(II) acetylacetonate as a precursor by supporting ca. 30 wt% Pt on our original MC, which was made from the self-organization formaldehyde/resorcinol and Pluronic F127.<sup>2</sup> The resulting electrocatalyst was named as Pt/MC and used as a cathode catalyst. For the anode, a commercially available Pt/Ketjen black catalysts (TEC10E50E, TKK Corp.) was in use. Membrane electrode assemblies (MEAs) were prepared by spraying the dispersion containing catalyst and Nafion ionomer on both sides of Nafion membrane. For the comparison, Pt deposited on commercial available Vulcan XC72 carbon black (Pt/VC) was also made and used as a cathode catalyst.

Current-voltage (IV) characteristics of MEAs were measured in this study. Initial IV characteristic of Pt/MC-MEA resulted in same as that of Pt/VC-MEA after optimizing the MEA preparation condition. In order to evaluate durability of MEAs, accelerating degradation tests were performed using potential cycles between 0.6 and 1.0 V vs RHE, where dissolution and re-precipitation of Pt particles occur.<sup>3</sup> During the durability evaluation, IV performance of Pt/MC-MEA momentarily went down probably owing to the flooding problem. Therefore, ohmic loss, concentration loss, and overvoltage were analyzed separately after ohmic resistance was found by impedance measurements. As expected, increase in concentration loss, most likely derived from the flooding, was observed when IV performance went down momentarily. When the change in overvoltage was compared, the overvoltage was lower for Pt/MC-MEA than Pt/VC-MEA in all the cases after 5000, 20000, and 40000 cycles. Therefore, encapsulation of Pt nanoparticles into carbon nanochannels was successfully increased durability.

Change in size of Pt particles before and after 40000 potential cycles was evaluated by TEM images. As seen Figure 1, the size of Pt particles in Pt/MC increased after the potential cycle, but some of them increased more and others did less. Then, surface and transmitted images were obtained at the same position in order to evaluate Pt size change inside the nanochannels, and so the growth of Pt particles was found much suppressed within the nanochannels, which is most likely due to reduced Pt mobility inside the nanochannels.

# Role of Interfaces of Au@Pt Nanoparticles in the Electrocatalysis of Alcohol Oxidation

Lingyi Peng, Hao Yang, Jia Li, Hongda Du, Lin Gan\*

*Division of Energy and Environment, Graduate school at Shenzhen, Tsinghua University, Shenzhen 518055, PR China*

*Email: lgan@sz.tsinghua.edu.cn*

Pt monolayers deposited on gold substrate (denoted as Au@Pt<sub>ML</sub>) have shown promising electrocatalytic activities on alcohol electro-oxidation due to the previously established lattice strain effect.<sup>1</sup> While Au@Pt<sub>ML</sub> have been constructed by under potential deposition of a Cu monolayer on Au{111} single crystal and subsequent galvanic displacement by Pt, the Pt overlayers deposited on Au nanoparticles in a similar way formed three-dimensional nanoclusters (denoted as Au@Pt<sub>cluster</sub>) instead of a monolayer. Such Au@Pt<sub>cluster</sub> may exhibit different electrocatalytic properties from the previously well-studied Au@Pt<sub>ML</sub> counterpart. Here, we showed that the Au/Pt interface formed by the supported Pt nanoclusters and the underling Au nanoparticles could play a previously overlooked important role during the electrocatalysis of alcohol oxidation. By increasing the coverage of the supported Pt nanoclusters on the Au nanoparticles, the specific activities for methanol oxidation and ethanol oxidation increased first and then decreased. This trend cannot be fully accounted by the previously established strain effect, but instead is in a good consistency with the trend of the Au/Pt interface density. Density functional theory calculations prove that the toxic CO<sub>ad</sub> intermediate formed during alcohol oxidation shows a higher binding energy on the Au/Pt interface than that adsorbed on the nearby Pt surface. These results suggest that the toxic CO<sub>ad</sub> intermediate could transfer from the catalytic Pt sites to the Au/Pt interface site, leading to increased available Pt sites for efficient alcohol oxidation electrocatalysis and thus increased catalytic activity.

Poly[2,2'-(p-phenylene)-5,5'-bibenzimidazole] (p-PBI) has superior tensile strength because of its para-oriented structure and has attracted much interest in recent years. However, p-PBI polymer which shows low solubility in organic solvent only can dissolved in strong acids, such as methanesulfonic acid. Consequently, a direct-casting method (also called sol-gel method) was proposed to prepare the PA doped p-PBI membrane from the high temperature polymerization solutions in polyphosphoric acid. In this study, we compared the properties of p-PBI and meta-PBI membranes that were fabricated by direct-casting method. Moreover, we investigated the performance of these membranes in high temperature proton electrolyte membrane fuel cell. The acid doping levels and proton conductivity of p-PBI membrane by direct-casting are around 30 mol PA/PRU and its proton conductivity is around  $0.2 \text{ S cm}^{-1}$  at around  $160^\circ\text{C}$ . The effects of casting process variables on membrane properties were also investigated by atomic force microscopy measurement. The enhanced single cell performance of p-PBI membrane is attributed to the high proton conductivity of p-PBI by direct-casting method.

# Synthesis and Characterization of Carbon-Based Non-Precious-Metal Cathode Catalysts from Polyimide Fine Particles

One major problem for polymer electrolyte membrane fuel cells in commercial applications is the cost and scarcity of platinum, which is used as the cathode catalyst, and the development of precious-metal-free cathode catalysts is strongly desired. We have explored the synthesis of a carbon-based catalyst from polyimide fine particles. Polyimide is a thermo resistive polymer and the morphology of precursor can be retained even after the carbonization; therefore, finer morphology can be expected.

Polyimide fine particle was prepared as shown in Figure 1. Fine nano-particles around 100-150 nm were successfully prepared. Thus obtained precursor was converted into a carbon-based catalyst by the multi-step pyrolysis<sup>1)</sup>.

Figure 2 shows the performance of a fuel cell with the developed cathode catalyst. The cell exhibits good fuel cell performance ( $1.0 \text{ A cm}^{-2}$  at 0.6 V and 80 °C) along with promising durability<sup>2)</sup>.

Thus obtained materials have been fully characterized by spectroscopy such as XPS and X-ray adsorption, and the detailed data will be discussed in the presentation.

## 1. Introduction

Polymer electrolyte fuel cells (PEFCs) are expected as one of the clean, highly effective energy conversion systems, and are developed intensively. However many problems remain to be solved before commercialization of PEFCs. Hydrogen peroxide formation at anode and cathode in PEFCs is one of the most important issues for the durability of the MEA in PEFC. We reported that larger amount of hydrogen peroxide formed as an intermediate in oxygen reduction reaction (ORR) on the electrode with lower catalyst loadings<sup>1, 2)</sup>. In present study, we evaluated the ORR activity on prepared electrodes with different Pt/C loadings by RRDE technique, and examined H<sub>2</sub>O<sub>2</sub> formation path in ORR.

## 2. Experimental

Commercially available 50 wt% Pt/C (TKK Inc, TEC-10E50E) catalyst was used in RRDE measurement. The RRDE consist of a glassy carbon (GC) disk electrode and a Pt ring electrode. An aliquot of the ultra-sonicated catalyst ink was carefully dropped on the GC disk electrode to adjust each Pt/C loading densities. Linear sweep voltammetry was performed from 0.05 to 1.0 V at 10 mV s<sup>-1</sup> in O<sub>2</sub> saturated 0.1 M HClO<sub>4</sub> to investigate ORR and hydrogen peroxide formation on Pt/C catalyst with different loadings by RRDE technique, and then a ring electrode potential was hold at 1.2V. Similar voltammetric measurement from 0.05 to 1.4 V at 10 mVs<sup>-1</sup> was carried out to evaluate hydrogen peroxide reduction reaction (HPRR) in deaerated 0.1M HClO<sub>4</sub> solution with H<sub>2</sub>O<sub>2</sub> additive by RDE technique.

## 3. Results and Discussion

Fig. 1 shows CVs per mass of Pt on prepared electrode with different catalyst loadings. A characteristic behavior such as hydrogen adsorption/desorption, Pt oxide formation and its reduction were observed on each samples, and then the current of CV per mass of Pt was almost equal to each catalyst loadings. Therefore, each electrode at different catalyst loadings was successfully modified on GC disk electrode. Fig. 2 shows H<sub>2</sub>O<sub>2</sub> formation rate measured by RRDE technique. An amount of H<sub>2</sub>O<sub>2</sub> formation was larger with lowering disk potential and decreasing catalyst loading on GC substrate. Fig. 3 shows LSV measurement results in HPRR. Hydrogen peroxide reduction current at catalyst loading of 1.41 μg<sub>Pt</sub> cm<sup>-2</sup> was lower than diffusion limiting current calculated value from Levich equation. Therefore, the HPRR was drastically affected by catalyst loadings compared with the ORR.

Fig. 1 CVs on 46 wt% Pt/C catalysts with different catalyst loadings on GC in Ar saturated 0.1 M HClO<sub>4</sub>. Scan rate : 50 mV s<sup>-1</sup>.

Fig. 2 The ratio of H<sub>2</sub>O<sub>2</sub> formation during ORR on 46wt% Pt/C with different catalyst loadings on GC in O<sub>2</sub> saterated 0.1 M HClO<sub>4</sub>. Rotating rate : 1600 rpm.

Fig. 3 Hydrogen peroxide reduction current on 46wt% Pt/C catalyst loaded at 1.41 and 14.1 μg cm<sup>-2</sup>. Rotating rate:1600 rpm.

## Introduction

Layered Double Hydroxides (LDHs) have been studied by many researchers for their interesting properties such as ion exchangers, adsorbents, polymer stabilizer, catalyst, and so on. LDHs are well known as anionic clays include anion species and water molecules in the interlayer which consist of positively charged metal hydroxide layers. It was reported that some types of LDHs prepared by co-precipitated method have high OH<sup>-</sup> conductivity and high performance as electrolyte for Alkaline Fuel Cells (AFCs) by Tatsumisago *et. al.*. Co-precipitation method is generally used for LDH synthesis, while we reported Electrochemical co-precipitated method which enable to form LDH thin film on an electrode surface<sup>2)</sup>. Therefore, we prepared Mg-Al LDHs by electrochemical co-precipitation method and evaluated their OH<sup>-</sup> conductivity.

## Experiments

The LDH was synthesized by co-precipitation and electrochemical co-precipitation method. In co-precipitation method, 0.075 mol dm<sup>-3</sup> Mg(NO<sub>3</sub>)<sub>2</sub> + 0.025 mol dm<sup>-3</sup> Al(NO<sub>3</sub>)<sub>3</sub> solution was stirred under Ar atmosphere. After deaeration, NaOH aq. was added and held the pH ca. 10 and aged the solution at 80 °C for 18h to synthesized the LDH. Electrochemical co-precipitation method is as following, Pt sheet was used as a working electrode and immersed in a 0.10 mol dm<sup>-3</sup> aqueous solution containing Mg(NO<sub>3</sub>)<sub>2</sub> and Al(NO<sub>3</sub>)<sub>3</sub> under Ar atmosphere. Galvanostatic electrolysis was carried out at -16 mA cm<sup>-2</sup> for 10 min. The crystalline structure and surface morphologies on the prepared samples were evaluated by XRD and SEM, respectively. The conductivity of prepared samples were measured by the AC impedance method at the 60 °C under the RH = 80%.

## Results and discussion

Fig. 1 shows XRD patterns of the electrochemical co-precipitated thin film on the Pt surface and co-precipitated sample. Characteristic peaks 11° (003) and 22° (006) in LDH is observed on both samples, therefore Mg-Al LDH is successfully synthesized by electrochemically and chemically method. Fig. 2 shows SEM image on (a) electrochemical co-precipitated LDH and (b) co-precipitated Mg-Al LDH. A plate-like shape was observed on both samples. Ion conductivity of Mg-Al LDH at 60°C under RH = 80% are shown in Fig. 3. Electrochemically co-precipitated LDHs have a little smaller conductivity than co-precipitated samples, while LDHs which prepared at x = 0.25 of Mg<sub>1-x</sub> - Al<sub>x</sub> LDH composition have a highest conductivity on each sample.

Fig. 1 XRD patterns of electrochemical co-precipitated sample and co-precipitated sample.

Fig. 2 SEM images on (a) Electrochemical co-precipitated sample and (b) co-precipitated sample.

Fig. 3 Ion conductivity on co-precipitated LDH and electrochemical co-precipitated LDH at 60°C under 80%RH.

Strontium titanate perovskite oxides have attracted a lot of interest as serious candidates to overcome the limitations of the state-of-the-art Ni-YSZ cermet, especially at intermediate temperatures. Co-doping the A site of strontium titanate with La and Ca resulted in an electronic conductivity of  $37 \text{ S.cm}^{-1}$  at  $600^\circ\text{C}$  [1].

In this paper, we aim to further increase the anodic performance of this material by additionally co-doping the B site with Ni and Nb. The expected exsolution of Ni nanoparticles is believed to boost the catalytic activity, while the Nb doping would increase the electronic conductivity. Therefore,  $\text{La}_{0.2}\text{Sr}_{0.25}\text{Ca}_{0.45}\text{Ti}_{1-x-y}\text{Nb}_x\text{Ni}_y\text{O}_3$  powders were synthesized using the solid-state reaction route. Structural, electrical, thermo-mechanical and electrochemical characterizations are performed to evaluate the potentiality of this material as anode component for intermediate temperature solid oxide fuel cells.

# Effects of Solvents for Dispersion Solutions on Membrane-Electrode Assembly for Proton Exchange Membrane Fuel Cells – Overvoltage and Durability

Gyu-Hyeon Oh, Mun-Sik Shin, Moon-Sung Kang, Jin-Soo Park\*

*Department of Environmental Engineering, College of Engineering, Sangmyung University, 31 Sangmyungdae-gil, Dongnam-gu, Cheonan, Chungnam Province 330-720, Republic of Korea*

*\*energy@smu.ac.kr*

Proton exchange membrane fuel cells (PEMFCs) is currently considered as a potential next-generation alternative energy technology because of the high energy density and high abundance of hydrogen in nature. One of the most important parts in PEMFCs is membrane-electrode assembly (MEA) which provides the electrochemical reactions at electrode, the permeation of fuel and/or oxidant gas and the drainage of water product. The structure of electrode in MEA significantly determines the performance of PEMFCs. In MEA, Nafion dispersion is the most widely used as the ionomer binder for catalyst inks. A high performance MEA requires the combination of performance and durability. The former could be achieved by reducing overvoltages, and the latter by reducing electrode cracking. The structure of electrodes in MEA significantly determines the performance and durability of PEMFCs. Electrode structure of MEA, including the pt-ionomer interface, could be determined when electrodes are solidified from catalyst inks during a drying step. Thus, the properties of the solvent system in catalyst inks play an important role in determining the electrode structure in MEA. The solvent system is mainly influenced by the solvents in polymer dispersions. The various solvents for catalyst inks were used and investigated the performance and durability of electrolyte membranes prepared by the casting of Nafion polymer solutions using the various solvents. The properties of membranes were investigated in terms of proton conductivity, mechanical stability, chemical stability, ect.

Much efforts are recently devoted to alkaline fuel cells using anionic polymeric membranes. Solid alkaline fuel cells (SAFCs) are operated in the same principle of alkaline fuel cells, but use solid type electrolytes. SAFCs have the advantages that are easier to handle systems at low operating temperatures (roughly room temperature  $\sim 70^\circ\text{C}$ ), to have higher reaction kinetics at the electrodes than proton exchange membrane fuel cells (PEMFCs) and to use non-noble metal catalysts. In addition, SAFCs are recently being highlighted to overcome the disadvantages of carbonate precipitates, leakage of liquid KOH electrolyte, and system complexity by using solid electrolytes. This solid electrolytes were prepared by quaternized polymers having a function to exchange anions. According to the recent works, alkaline doped PBI membranes exhibited good ionic conductivity, acceptable mechanical strength, high thermal stability, and low methanol permeability.

For fuel cell applications, membrane-electrode assemblies should be prepared for solid alkaline fuel cells. However, few researches on ionomer binder solutions for preparation of electrodes of MEAs were carried out.

In this study, new anion conducting polymer were synthesized using quaternized polymers as ionomer binder. A quaternized polybenzimidazoles (PBIs) having quaternized intermediate 4-methyl-4-glycidylmorpholin-4-ium chloride (MGMC) in the main-chain and/or in the side group were synthesized for use as anion conducting ionomer binder for SAFCs. The quaternized polymers were investigated in terms of ionic conductivity, IEC, FT-IR, NMR etc. The thermal stability, mechanical properties, hydroxide conductivity and membrane stability were also investigated.

# Copper-Incorporated Carbon Catalysts for Oxygen Reduction Reaction

Marika Muto, Masaru Kato, Ichizo Yagi

Graduate School of Environmental Science, Hokkaido University

N10W5 Sapporo 060-0810 Japan

m-Muto@ees.hokudai.ac.jp

Platinum metal group (PMG) catalysts are used for oxygen reduction reaction (ORR) at cathodes in state-of-the-art polymer electrolyte fuel cells (PEFCs). Since the PMG catalysts contain expensive rare metals, they should be replaced with rare-metal-free catalysts for widespread PEFCs. Recently, electrocatalysts synthesized from carbon and transition metal complexes have been studied [1,2]. It is known that ORR catalysts with multi-nuclear-active sites have high ORR activity [3]. It is also known that natural ORR catalysts such as laccases have a multinuclear copper complex as an active center and show high ORR activity [4], suggesting that laccase-inspired artificial ORR catalysts prepared from carbon and a multi-nuclear copper complex would show high ORR activity.

In this work, we incorporated a trinuclear copper complex ( $[\text{Cu}_3(\text{trz})_3(\mu_3\text{-OH})]\text{Cl}_2 \cdot 6\text{H}_2\text{O}$ , Fig. 1) [5] into graphene nanosheets to synthesize laccase-inspired electrocatalysts for ORR, where graphene nanosheets worked as an electrical conductive material and the trinuclear copper complex with a triangle core imitated the active center of laccases.

The trinuclear copper complex was prepared from copper chloride and 1,2,4-triazole according to the literature [5]. This copper complex and graphene oxide (GO) were mixed and then reduced in two methods. The first method is heat treatment at high temperature (1173 K) for a short time (45 s). The second method is electrochemical reduction on a glassy carbon (GC) electrode (-1.1 V vs.  $\text{Ag}|\text{AgCl}$ , 300 s). We carried out powdery X-ray diffraction (XRD) analysis, X-ray photoelectron spectroscopy (XPS) and inductively coupled plasma atomic emission spectroscopy (ICP-AES) to characterize the catalysts. For electrochemical measurements of the catalysts, the powdery catalyst was suspended in an ethanol-Nafion mixture to make ink containing the catalyst. The catalyst ink was put on a GC electrode and dried under the air at room temperature. Linear Sweep Voltammetry (LSV) was carried out under a saturated  $\text{O}_2$  atmosphere using a rotary disk electrode to obtain current-potential curves. Britton-Robinson buffered solutions were used as electrolyte solutions.

The heat or electrochemical reduction improved ORR activity. The catalyst obtained after the heat treatment showed higher ORR activity than that obtained after the electrochemical reduction. This result indicated that the two reduction methods might give different structures of ORR active sites. XPS spectra of the catalyst before and after the heat treatment were recorded to obtain information on structural changes. A peak originating from C-O was observed before the heat treatment. It disappeared after the heat treatment. This result indicated that GO was reduced to rGO by the heat treatment. The  $\text{Cu}2\text{p}$  spectra showed that  $\text{Cu}^{\text{II}}$  was also reduced to  $\text{Cu}^{\text{I}}$ . A new peak was observed in N1s spectra after the heat treatment. This peak might be attributed to new configuration that triazole rings were incorporated into graphene nanosheets.

We measured LSV of the heat-treated catalyst in a wide range of pHs (pH 1 to pH 13) to understand pH-dependence of the ORR activity. The highest ORR activity was observed at pH 13.

Fig. 1 Coordination structure of  $[\text{Cu}_3(\text{trz})_3(\mu_3\text{-OH})]\text{Cl}_2 \cdot 6\text{H}_2\text{O}$

# Oxygen reduction reaction on Au@Pt nanoparticles and Au(100) electrode

Yong Li Zheng, Yao Yao, Dong Mei and Yan-Xia Chen\*

*Hefei National Laboratory for Physical Science at Microscale and Department of Chemical Physics, University of Science and Technology of China, Hefei, 230026, China*

[yachen@ustc.edu.cn](mailto:yachen@ustc.edu.cn)

Oxygen reduction reaction (ORR) at Au@Pt nanoparticles (NPs) and the redox reaction of hydrogen peroxide ( $\text{O}_2 + 2\text{H}^+ + 2\text{e}^- \rightleftharpoons \text{H}_2\text{O}_2$ ) at Au(100) electrode/0.1 M  $\text{HClO}_4$  interface have been investigated. On Au@Pt NPs, we found that the Au@1 ML Pt NPs in the series of Au@0.7-4 ML Pt NPs has the best ORR activity and its half wave potential for ORR is found to be ca. 30 mV more positive than that for pc-Pt and 20% Pt/C. XPS and SERS study revealed that the enhancement of ORR activity at Au@Pt nanoparticle originate from the charge transfer from Au core to Pt shell.

On Au(100) electrode, we found that i) the kinetics for electrochemical oxidation of  $\text{H}_2\text{O}_2$  to  $\text{O}_2$  is very fast, which occurs at potential very close to its equilibrium potential ( $E_{\text{O}_2/\text{H}_2\text{O}_2}^{\text{eq}}$ ); ii) the kinetics for  $\text{O}_2$  reduction to  $\text{H}_2\text{O}_2$  is much slower than that for  $\text{H}_2\text{O}_2$  oxidation with H-D kinetic isotope effect of above two; iii) the onset overpotential of  $\text{H}_2\text{O}_2 + 2\text{H}^+ + 2\text{e}^- \longrightarrow 2\text{H}_2\text{O}$  is ca. 1.4 V. The origin for the high overpotential at the onset for  $\text{O}_2$  reduction at Au(100) is limited by the thermodynamic equilibrium potential for  $\text{O}_2 + 2\text{H}^+ + 2\text{e}^- \rightleftharpoons \text{H}_2\text{O}_2$  due to the fast kinetics of  $\text{H}_2\text{O}_2$  oxidation.

# Improvement on corrosion resistance and conductivity by electroplated coatings on aluminum 5052 bipolar plate of proton exchange membrane fuel cell

Kung-Hsu Hou, Hsiang-Cheng Wang, Ming-Der Ger, Chen-En Lu  
*Chung-Cheng Institute of Technology, National Defense University*  
*No.75, Shihyuan Rd., Dasi Dist., Taoyuan City 33551, Taiwan (R.O.C.)*  
*khou@ndu.edu.tw*

In this study, the trivalent Cr-C coatings were electroplated on aluminum 5052 substrate for an application of BPPs because of their excellent electric conductivity and corrosion resistance. The corrosion behavior of the BPPs with and without Cr-C coatings was measured by liner polarization and potentiodynamic measurements. The SEM images of surface morphology showed that the thickness of the coating was about 1.1 to 3.5  $\mu\text{m}$  and increased with raising coating current density. The surface morphology at 10  $\text{A}/\text{dm}^2$  is without cracks and pinholes happened than those at 30  $\text{A}/\text{dm}^2$  and 50  $\text{A}/\text{dm}^2$ . Moreover, the polarization curve with different current density (10, 30, 50  $\text{A}/\text{dm}^2$ ) represented the coating prepared at 10  $\text{A}/\text{dm}^2$  and 10 minutes possessing the lowest corrosion current density ( $I_{\text{corr}}=3.67 \times 10^{-7} \text{ A}/\text{cm}^2$ ). Interfacial contact resistance (ICR) of the bipolar plate coated with Cr-C coating at 10  $\text{A}/\text{dm}^2$  is improved obviously, presenting an ICR of 19.48  $\text{m}\Omega\text{cm}^2$  under 138  $\text{N}/\text{cm}^2$  which is superior to the others and less than the standard of DOE (10  $\text{m}\Omega\text{cm}^2$ ). The results of scanning electron microscope (SEM) and ICR before and after corrosion tests indicate that the aluminum 5052 bipolar plate with Cr-C coating is considerably stable electrochemically.

Keywords: Electroplating, Cr-C coating, Corrosion resistance, Bipolar plates, PEMFC.

## Introduction

Development of non-platinum electrocatalysts for oxygen reduction reaction (ORR) is required for real commercialization of polymer electrolyte fuel cells. We have focused on group 4 and 5 metal oxide-based compounds<sup>1)</sup>, because they have high chemical stabilities in acidic media and are less costly than platinum. In order to obtain high durable catalysts, we proposed oxide-based cathodes without carbon<sup>2)</sup>. Although both creation of active sites and formation of electro-conductive paths are necessary to act as actual cathodes, it is difficult to optimize them simultaneously. In this study, we focused on the formation of the active sites for the ORR to investigate the conditions at which the ORR generates by preparing titanium-niobium oxides.

## Experimental

30 cm<sup>3</sup> of Titanium(IV) Isopropoxide (99.99%, Aldrich) and 4 cm<sup>3</sup> of Niobium(V) pentaethoxide (99.99%, Aldrich) were mixed in 30 cm<sup>3</sup> of 2-Methoxyethanol to be TiO<sub>2</sub>:Nb<sub>2</sub>O<sub>5</sub> = 8:2 as a precursor solution. 2-Methoxyethanol solution dispersed with Ti-Nb oxide particles was prepared according to the sol-gel method<sup>3)</sup> as a catalyst ink. The ink was dropped on a glassy carbon rod. After drying the ink, it was heat-treated at 1050, 800, 600 °C in air and at 1050, 800, 700, 600 °C in 4%H<sub>2</sub>/Ar to obtain working electrodes. All electrochemical measurements were performed in 0.1 mol dm<sup>-3</sup> H<sub>2</sub>SO<sub>4</sub> at 30 °C with a 3-electrode cell. A reversible hydrogen electrode (RHE) and a glassy carbon plate were used as the reference and the counter electrodes, respectively. Slow scan voltammetry (SSV) was performed with a scan rate of 5 mV s<sup>-1</sup> from 0.2 to 1.2 V vs. RHE under O<sub>2</sub> and N<sub>2</sub> atmosphere to obtain ORR current. The ORR current density (*i*<sub>ORR</sub>) was based on the electric charge of the double layer capacitance of the oxides.

## Results and discussion

Figure 1 shows the potential-*i*<sub>ORR</sub> curves of Ti-Nb oxides heat-treated at 1050, 800, 600 °C in air (air) and at 1050, 800, 700, 600 °C in 4%H<sub>2</sub>/Ar (red). The Ti-Nb oxides heat-treated in air showed no ORR current below 0.6 V. On the other hand, the ORR current was observed over 0.8 V by the heat-treatment in 4%H<sub>2</sub>/Ar, and the ORR activities changed by the temperature. Therefore, we found that the heat-treatment under reductive atmosphere produced the ORR activity, and the heat-treatment temperature of 700 °C was suitable for achieving high ORR activity. These results suggest that the emergence of the ORR activity is related to the appropriate reduction of Ti and/or Nb nearby surface.

Fig.1 Potential-*i*<sub>ORR</sub> curves of specimens prepared at 1050, 800, 700, 600 °C in 4%H<sub>2</sub>/Ar and at 1050, 800, 600 °C in air.

## Introduction

Development of non-precious metals and carbon free cathodes as alternative materials of platinum supported carbon catalysts is required for practical application of polymer electrolyte fuel cells (PEFCs). Thus, we prepared the oxide based catalysts which were composed of niobium-titanium oxides with active sites and titanium oxides with magneli phase of  $\text{Ti}_4\text{O}_7$  as electric conductive<sup>1</sup> ( $\text{Ti}_x\text{Nb}_y\text{O}_z + \text{Ti}_4\text{O}_7$ ).

We revealed that the  $\text{Ti}_x\text{Nb}_y\text{O}_z + \text{Ti}_4\text{O}_7$  catalysts exhibited high durabilities in 0.1 mol dm<sup>-3</sup>  $\text{H}_2\text{SO}_4$  at 30 °C.<sup>2</sup> However, we have not evaluated yet the durabilities of these catalysts at higher temperature, 80 °C, which is a close to real PEFC conditions. In addition, a glassy carbon (GC) rod commonly used as a substrate was severely oxidized at 80 °C. We therefore used a  $\text{Ti}_4\text{O}_7$  rod as a substrate because of its high stability and conductivity<sup>1</sup>. In this study, we evaluated the durability of the  $\text{Ti}_x\text{Nb}_y\text{O}_z + \text{Ti}_4\text{O}_7$  in 0.1 mol dm<sup>-3</sup>  $\text{H}_2\text{SO}_4$  at 80 °C using the  $\text{Ti}_4\text{O}_7$  rod as the substrate.

## Experimental

$\text{Ti}_x\text{Nb}_y\text{O}_z + \text{Ti}_4\text{O}_7$  catalysts were prepared by dry ball-milling with  $\text{TiO}_2$  and  $\text{Nb}_2\text{O}_5$  powder mixture and reductive heat-treatment in 4%  $\text{H}_2/\text{Ar}$  at 1050 °C for 50 h.<sup>2</sup> The powder catalysts were supported about 0.1 mg on the top of the  $\text{Ti}_4\text{O}_7$  rod. In order to evaluate the electrochemical stabilities of the catalysts in 0.1 mol dm<sup>-3</sup>  $\text{H}_2\text{SO}_4$  at 80 °C, a start-stop cycle test<sup>3</sup> (triangular wave, 1.0 - 1.5 V vs. reversible hydrogen electrode (RHE),  $\text{N}_2$ , a scan rate: 0.5 V s<sup>-1</sup>) and a load cycle test<sup>3</sup> (rectangular wave, 0.6 - 1.0 V vs. RHE,  $\text{O}_2$ , holding time: 3 s) were performed as degradation tests using a 3-electrode cell. An RHE and a GC plate were used as the reference and the counter electrodes, respectively. During the degradation tests, chronoamperometry at 0.7 V under  $\text{O}_2$  atmosphere was performed to evaluate the catalytic activity of oxygen reduction reaction (ORR). The durability was evaluated by a ratio of  $i_{\text{ORR}} @ 0.7 \text{ V}$  during degradation test to that at initial,  $N_{i_{\text{ORR}} @ 0.7 \text{ V}}$ .

## Results and discussion

Fig. 1 shows the variation of  $N_{i_{\text{ORR}} @ 0.7 \text{ V}}$  of the  $\text{Ti}_x\text{Nb}_y\text{O}_z + \text{Ti}_4\text{O}_7$  during start-stop and load cycle tests. In both tests, the values of the  $N_{i_{\text{ORR}} @ 0.7 \text{ V}}$  slightly changed during the initial potential cycling up to 2500 cycle. However, these values kept 1 above 5000 up to 20000 cycle, indicating that the  $\text{Ti}_x\text{Nb}_y\text{O}_z + \text{Ti}_4\text{O}_7$  had superior stability for both start-stop and load cycle tests in 0.1 mol dm<sup>-3</sup>  $\text{H}_2\text{SO}_4$  at 80 °C. Therefore, we successfully demonstrated that the active sites on the titanium-niobium oxides are highly stable both low and high potential regions at 80 °C. In other words, non-precious metals and carbon-free cathodes based on Group 4 and 5 metal oxides have essentially high durability as we expected.

## Introduction

Development of non-noble metal cathodes as alternative materials of platinum is required for practical application of polymer electrolyte fuel cells. We found that the titanium oxide-based compounds with multi-walled carbon nanotubes ( $\text{TiC}_x\text{N}_y\text{O}_z/\text{MWCNTs}$ ) prepared from oxy-titanium tetra-pyrazino-porphyrazine (TiOTPPz) with heat treatment under low oxygen partial pressure showed high oxygen reduction reaction (ORR) activity [1, 2]. However, the ORR mechanism on the titanium oxide-based catalysts has not yet analyzed in detail. In this study, we tried to investigate the ORR mechanism on the  $\text{TiC}_x\text{N}_y\text{O}_z/\text{MWCNTs}$  by using rotating ring disk electrode (RRDE) method.

## Experimental

TiOTPPz and multi-walled carbon nanotube (MWCNT) were mixed and conducted dry-ball-milling. The mixture was heated to 900 °C under Ar and then kept under Ar containing 0.05% $\text{O}_2$  and 2% $\text{H}_2$  for several hours. All electrochemical measurements were performed using an RRDE cell contained 0.1 mol  $\text{dm}^{-3}$   $\text{H}_2\text{SO}_4$  at 30 °C. Cyclic voltammetry was performed in  $\text{O}_2$  or  $\text{N}_2$  from 0.2 to 1.2 V vs. RHE (reversible hydrogen electrode) at a scan rate of 5  $\text{mV}\cdot\text{s}^{-1}$ . These measurements were performed in the same manner as previously described [3].

## Results and discussion

Fig.1 shows disc and ring currents as a function of disc potentials for oxygen reduction on  $\text{TiC}_x\text{N}_y\text{O}_z/\text{MWCNT}$  prepared with 3 h oxidation. We calculated the hydrogen peroxide formation rate,  $x_{\text{H}_2\text{O}_2}$ , from the disk and ring current in Fig. 1. Then, the  $x_{\text{H}_2\text{O}_2}$  @0.6V was approximately 10% at 1600 rpm. In addition, we estimated the individual rate constants of ORR ( $k_1$ ,  $k_2$ , and  $k_3$ ) based on the Damjanovic model [3, 4, 5]. These constants correspond to four electron reduction of oxygen, two electron reduction of oxygen, and reduction of hydrogen peroxide, respectively. The value of  $k_1/k_2$  means the selectivity of four electron reduction of oxygen. The value of  $k_1/k_2$  on the  $\text{TiC}_x\text{N}_y\text{O}_z/\text{MWCNT}$  was approximately 7 and almost similar to that of the platinum catalyst [4]. Consequently, we revealed that the  $\text{TiC}_x\text{N}_y\text{O}_z/\text{MWCNTs}$  have high selectivity of four electron reduction.

Polymer electrolyte membrane fuel cell (PEMFC) is one of the promising energy conversion systems due to high efficiency and environmental compatibility [1]. However, the current PEMFC uses commercialized perfluorosulfonic acid (PFSA) polymers as a proton exchange membrane, which has the issues of high production cost, poor recyclability, and limited operational temperature [2]. And also the fuel cell performance under elevated temperature condition is poor because of low water management and low T<sub>g</sub> [3]. Thus, in order to achieve high PEMFC performance, the proton conductivity under low relative humidity should be improved. We can solve this problem using non-fluorinated hydrocarbon membrane. Because it has a good thermal stability, low cost, and good durability at intermediate temperature. Although it has good properties, but its fuel cell performance is lower than PFSA based membranes due to its low proton conductivity. To solve this problem, non-fluorinated membrane containing partially asymmetric chemical structure and sulfonated block copolymer was prepared and characterized using <sup>1</sup>H-NMR; eventually studied for PEMFC at intermediate temperature. Sulfonated block copolymer exhibits an excellent proton conductivity under 70-100% RH as well as good power density when FC operating under 75-100% RH. Other parameters such as water uptake, ion exchange capacity (IEC) and morphology will be discussed in this presentation.

[nick.daems@biw.kuleuven.be](mailto:nick.daems@biw.kuleuven.be)

Proton-exchange membrane fuel cells (PEMFC) have attracted substantial attention in the last decades as a green and non-polluting power source, especially for application in vehicles [1]. A membrane is an essential component of a PEMFC, as it allows protons to pass from the anode half-cell to the cathode half-cell while avoiding reagents to interact directly with each other. Besides having a good proton conductivity, the membrane also needs to be chemically, mechanically and thermally stable. Nafion is generally the material of choice for manufacturing proton-exchange membranes (PEM) in fuel cells. However, due to its high cost, the development of cheaper membranes with comparable or better properties than those made of Nafion is highly important for the commercialization of fuel cells.

Here, we present sulfonated polyvinylidene fluoride (PVDF) membranes as a promising alternative for Nafion membranes in PEMFCs. The membranes were synthesized by means of the following steps: 1) synthesis of PVDF membrane by means of phase inversion; 2) PVDF activation with KOH and reaction with styrene and 3) sulfonation with chlorosulfonic acid to ultimately obtain a stable, proton-conducting membrane [1]. These materials display important assets: (1) the presence of a fixed PVDF matrix, which will limit membrane swelling; (2) PVDF is a rather cheap bulk product; (3) sulfonation throughout the whole membrane cross-section, which allows direct catalyst-proton conductor contact and could thus provide easy transfer of protons.

In the fuel cell setup, a membrane forms part of the membrane electrode assembly (MEA). The standard procedure to prepare MEAs is via hot or cold pressing of membrane, electrocatalyst and gas diffusion layer (GDL). This is a labour-intensive procedure that is hard to automate, leaving processing complicated. Moreover, all separate layers have to be mechanically stable, so membranes are intrinsically thick (typically more than 50  $\mu\text{m}$ ), hence showing poor mass transfer. Therefore, two novel, alternative techniques were tested to produce the MEAs: (1) dipcoating, in which the membrane is brought into contact with a dispersion containing a solvent, the electrocatalysts and poly(sodium 4-styrenesulfonate) and (2) binderless deposition, where a suspension containing the electrocatalyst and a solvent/swelling agent for PVDF is spread across the membrane surface.

SEM images of the sulfonated membranes (Fig. 1A) revealed that asymmetric membranes with a dense top layer and a porous supporting layer were successfully obtained in all cases. A first evaluation of the proton conductivity as a function of temperature of these new membranes compared to the state-of-the-art Nafion membranes (Fig. 1B), revealed that the PVDF membranes achieve similar or better conductivities than Nafion, especially at higher temperatures. These higher conductivities can be explained based on the higher number of acid sites in the sulfonated PVDF membranes, as proven by their higher ion exchange capacities (1.8 mmol/g) compared to Nafion (1.3 mmol/g). In the near future, the performance of these PEMs will be evaluated in a  $\text{H}_2/\text{O}_2$  fuel cell setup, as part of the MEA. Even if the evaluation of these cheaper membranes is still in its initial phase, their conductivity values already reveal that this type of membranes can be a very promising alternative to Nafion membranes.

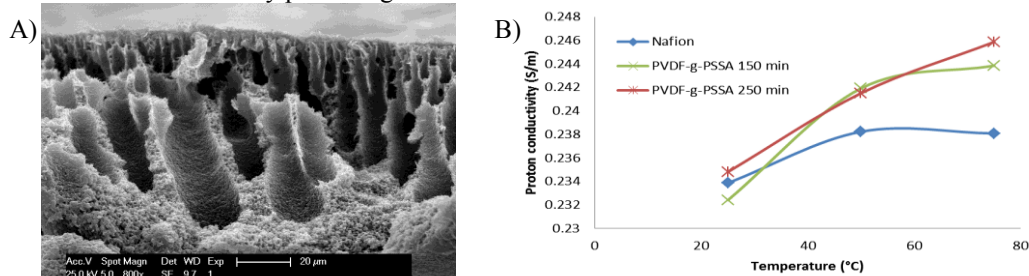

Figure 1: (A) SEM picture of PVDF-g-PSSA membrane and (B) comparison of conductivity as a function of temperature for Nafion and sulfonated PVDF membranes.

# Metalloporphyrin-Modified Perovskite-Type Oxide for Cathode Catalyst in Alkaline Fuel Cell

Tsukasa Nagai, Shin-ichi Yamazaki, Naoko Fujiwara, Masafumi Asahi, Zyun Siroma, and Tsutomu Ioroi  
*Research Institute of Electrochemical Energy, Department of Energy and Environment  
National Institute of Advanced Industrial Science and Technology (AIST)  
1-8-31, Midorigaoka, Ikeda, Osaka 563-8577, Japan  
tsukasa-nagai@aist.go.jp*

Alkaline fuel cell (AFC) has attracted attention due to the potential use of non-Pt-based catalyst. Perovskite-type oxides are considered one of the promising candidates for alkaline-resistant electrocatalyst with high oxygen reduction reaction (ORR) activity<sup>1</sup>. Recent researches on perovskite catalyst reported that the La-Mn based perovskite and La-Co based perovskite in carbon supported catalyst contributes to reduction and/or disproportionation of H<sub>2</sub>O<sub>2</sub><sup>2</sup>. Therefore, it may be possible to promote the overall reaction on a carbon-supported perovskite catalyst by adding a co-catalyst with high two-electron O<sub>2</sub> reduction activity. In this study, perovskite/carbon was modified by a cobalt octaethylporphyrin (Co-OEP) showing two electron O<sub>2</sub> reduction activity. ORR activity of the catalyst was investigated in alkaline media by a rotating ring disk electrode (RRDE) method.

The precursors of perovskite-type oxide (La<sub>0.6</sub>Sr<sub>0.4</sub>Mn<sub>0.6</sub>Fe<sub>0.4</sub>O<sub>3</sub>) were obtained by evaporating an aqueous solution of a mixture of La(NO<sub>3</sub>)<sub>3</sub>·6H<sub>2</sub>O, Sr(NO<sub>3</sub>)<sub>2</sub>, Mn(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, Fe(NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O, and polyvinyl pyrrolidone (PVP). The mixtures were heated in air at 600°C. The BET surface area of La<sub>0.6</sub>Sr<sub>0.4</sub>Mn<sub>0.6</sub>Fe<sub>0.4</sub>O<sub>3</sub> was measured to be 31 m<sup>2</sup> g<sup>-1</sup>. The perovskite/carbon (La<sub>0.6</sub>Sr<sub>0.4</sub>Mn<sub>0.6</sub>Fe<sub>0.4</sub>O<sub>3</sub>/C) was prepared by mixing La<sub>0.6</sub>Sr<sub>0.4</sub>Mn<sub>0.6</sub>Fe<sub>0.4</sub>O<sub>3</sub> and carbon black (Vulcan XC 72) in an agate pot at a rotation speed of 400 rpm for 30 min. Cobalt octaethylporphyrin (Co-OEP) was adsorbed on La<sub>0.6</sub>Sr<sub>0.4</sub>Mn<sub>0.6</sub>Fe<sub>0.4</sub>O<sub>3</sub>/C by an evaporation-to-dryness method. A glassy carbon electrode was used as a working electrode. A reversible hydrogen electrode (RHE) and a platinum electrode were used as a reference and counter electrodes, respectively.

The hydrodynamic voltammograms for the prepared catalysts show the onset potential of the Co-OEP/La<sub>0.6</sub>Sr<sub>0.4</sub>Mn<sub>0.6</sub>Fe<sub>0.4</sub>O<sub>3</sub>/C catalyst is shifted to positive direction and the ORR current was drastically increased, compared to the perovskite/C and Co-OEP/C catalyst. Decreased ring current was clearly confirmed relative to that for Co-OEP/C.
